Mr. Doweswell: It would be equally fair to say that the private practitioner puts it on to get the largest income he can. In precisely the same way we are entitled to as large a dividend as we legitimately can earn. He contended that the companies met a want. Supposing the Dental Bill passed into law, he suggested that a clause should be inserted to the effect that the General Medical Council should not prohibit fully qualified men from taking service with companies which advertised.

Mr. J. H. **Roberts**, solicitor to the Incorporated Society of Extractors and Adapters of Teeth, also appeared as a witness. He submitted that the registered practitioners were not sufficient for the needs of the country and that the members of his society filled the deficiency in a manner satisfactory to the public.

The committee then adjourned.

Appointments.

Successful applicants for Vacancies, Secretaries of Public Institutions, and others possessing information suitable for this column, are invited to forward to THE LANCET *Office, directed to the Sub-Editor, not later than 9 o'clock on the Thursday morning of each week such information for gratuitous publication.*

Braund, James Montague, M.R.C.S., L.S.A., has been re-appointed Medical Officer of Health for the Stratton (Cornwall) Rural District Council.

Calthrop, Lionel C. E., M.B. Durh., M.R.C.S., L.R.C.P., has been appointed Medical Superintendent of Woodhall Spa, Lincolnshire.

Crisp, James Ellis, M.R.C.S., L.S.A., has been re-appointed Medical Officer for the Lacock District by the Chippenham Board of Guardians.

Dawson, George W., F.R.C.S. Irel., D.P.H., has been appointed Surgeon to St. John's Hospital for Diseases of the Skin, Leicester-square, W.C.

Fairclough, W. A., M.B., Ch.B. N.Z., has been appointed House Surgeon at the Royal Westminster Ophthalmic Hospital.

Field, F. E., M.B., Ch.B. Edin., has been appointed Clinical Assistant at St. John's Hospital for Diseases of the Skin, Leicester-square, W.C.

Hare, T. G., M.D Freib., has been appointed Pathologist and Bacteriologist to St. John's Hospital for Diseases of the Skin, Leicester-square, W.C.

Hollick, Bernard Septimus, L.R.C.P. Lond., M.R.C.S., has been appointed Medical Officer of Health for the Sturminster (Dorset) *Rural District Council.*

Kelynack, T. N., M.D. Vict., M.R.C.P. Lond., has been appointed Honorary Physician and Medical Adviser to the Children's Home and Orphanage (London and nine country branches).

Richardson, M J, M.B., M.S. Edin., has been appointed Certifying Surgeon under the Factory and Workshop Act for the Wolston District of the county of Warwick.

Smith, W. Alexander, M.B., Ch.B. Aberd., has been appointed Assistant House Surgeon at the North Riding Infirmary.

Vacancies.

For further information regarding each vacancy reference should be made to the advertisement (see Index).

Birmingham City Asylum.—*Resident Clinical Assistant (female).* Salary £50 per annum, with apartments, board, and washing.

Birmingham General Hospital.—Three Receiving-rooms Officers. Salary £150 per annum.

Bolton Infirmary and Dispensary.—Junior House Surgeon. Salary £100 per annum, with apartments, board, and attendance.

Bradford Poor-law Hospital and Workhouse.—Resident Assistant Medical Officer, unmarried. Salary £100, with rations, apartments, and washing.

Bradford Royal Infirmary.—Resident Surgical Officer. Salary £150 per annum.

Bristol General Hospital.—Physician. Also Assistant Physician.

Canterbury City Asylum.—Assistant Medical Officer. Salary £140 per annum, with apartments and laundry.

Coventry and Warwickshire Hospital.—Junior House Surgeon. Salary £60 per annum, with rooms, board, washing, and attendance.

Dr. Barnardo's Homes.—House Surgeon and Resident Medical Officer at Her Majesty's Hospital for Children, Stepney Causeway, E. Salary £60, with board, lodging, and washing.

Dumfries and Galloway Royal Infirmary.—Assistant House Surgeon. Salary £25 per annum, with board and washing.

East London Hospital for Children and Dispensary for Women, Shadwell, E.—Assistant Surgeon. Also House Physician for six months. Salary £25, with board, residence, laundry, &c.

Egypt.—Sub-Inspector of Ophthalmic Hospitals, unmarried. Salary £500 a year.

Evelina Hospital for Sick Children, Southwark, S.E.—Clinical Assistants.

General Post Office, Medical Department (Male Staff).—Assistant to the Medical Officers at Headquarters. Salary £200 a year, rising to £300.

Gloucester, General Infirmary and Gloucestershire Eye Institution.—Senior House Surgeon. *Salary £100 per annum*, with board, residence, and washing.

Grimsby and District Hospital.—Resident House Surgeon. Salary £100 per annum, with board, lodging, and washing.

Guildford, Royal Surrey County Hospital.—House Surgeon. Salary £100, with board, residence, and laundry.

Guy's Hospital.—Gordon Lecturer on *Pathology.* Salary £500 per annum.

Hospital for Sick Children, Great Ormond-street, London, W.C.—House Surgeon, unmarried, for six months. Salary £20, with board and residence.

Hull, Royal Infirmary.—Casualty House Surgeon. Salary £50, with board and lodging.

Indian Medical Service.—An Examination for not less than 11 Commissions.

Ingham Infirmary and South Shields and Westoe Dispensary.—Senior House Surgeon. Salary £100 per annum, with residence, board, and washing.

Leicestershire and Rutland Asylum, Leicester.—Senior Assistant Medical Officer, unmarried. Salary £150, rising to £200, with board, apartments, and washing.

Lincoln County Hospital.—Junior House Surgeon, unmarried, for six months Salary £25, with board, residence, *and washing.*

Liverpool Eye and Ear Infirmary.—House Surgeon. Salary £80 per annum, with board and lodging.

London County Asylum, Horton, Epsom.—*Fifth Assistant Medical* Officer. Salary £150 a year, with board, apartments, and washing.

London School of Tropical Medicine.—Entomologist.

Loughborough and District General Hospital and *Dispensary.*—Resident House Surgeon. *Salary £100* a year, *with rooms*, attendance, board, and washing.

Macclesfield General Infirmary.—Junior House Surgeon. Salary £60 per annum, with board and residence.

Maidstone, West Kent General Hospital.—Assistant House Surgeon, unmarried. Salary £50, with board and lodging.

Miller Hospital and Royal Kent Dispensary, *Greenwich road*, S.E.—*Honorary* District Medical Officers.

North-East London Post-Graduate College (Prince of Wales's General Hospital, Tottenham, N.).—Cliniques:—10.30 A.M.: Medical Out-patient (Dr. Auld). 2.30 P.M.: Gynæcological Out-patient (Dr. Giles), Surgical Out-patient (Mr. Edmunds). Surgical Operations (Mr. Carson). 4.30 P.M.: Special Demonstration of X Ray Cases (Mr. Pirie).

London School of Clinical Medicine (Dreadnought Hospital, Greenwich).—2.15 P.M.: Dr. R. T. Howlett: Medicine. 2.30 P.M.: Operations. 3.15 P.M.: Mr. Carless: Surgery. 4 P.M.: Mr. M. Morris: Diseases of the Skin. Out-patient Demonstrations:—10 A.M.: Surgical and Medical. 12 noon: Skin. 2.15 P.M.: Special Lecture:—Dr. Howlett: Diagnosis of the Nature of Pathological Exudates.

Central London Throat and Ear Hospital (Gray's Inn-road, W.C.).—3.45 P.M.: Demonstration:—Mr. C. Nourse: Larynx.

National Hospital for the Paralysed and Epileptic (Queen-square, Bloomsbury, W.C.).—3.30 P.M.: Clinical Lecture:—Dr. Tooth: Multiple Neuritis.

WEDNESDAY (19th).—Post-Graduate College (West London Hospital, Hammersmith-road, W.).—10 A.M.: Dr. Ball: Diseases of the Throat, Nose, and Ear. Dr. Saunders: Diseases of Children. 2 P.M.: Medical and Surgical Clinics. X Rays. Mr. K. Scott: Diseases of the Eye. 2.30 P.M.: Operations. 5 P.M.: Lecture:—Dr. Beddard: Practical Medicine.

North-East London Post-Graduate College (Prince of Wales's General Hospital, Tottenham, N.).—Cliniques:—2.30 P.M.: Skin (Dr. Meachen), Eye (Mr. Brooks), Medical Out-patient (Dr. Whipham).

London School of Clinical Medicine (Dreadnought Hospital, Greenwich).—2.15 P.M.: Dr. F. Taylor: Medicine. 2.30 P.M.: Operations. 3.30 P.M.: Mr. Cargill: Ophthalmology. Out-patient Demonstrations:—10 A.M.: Surgical and Medical. 11 A.M.: Eye.

THURSDAY (20th).—Royal College of Physicians of London (Pall Mall East).—5 P.M.: Croonian Lecture:—Dr. W. J. R. Simpson: Plague.

Post-Graduate College (West London Hospital, Hammersmith-road, W.).—2 P.M.: Medical and Surgical Clinics. X Rays. Mr. Dunn: Diseases of the Eye. 2.30 P.M.: Operations. 5 P.M.: Lecture:—Mr. Baldwin: Practical Surgery.

North-East London Post-Graduate College (Prince of Wales's General Hospital, Tottenham, N.).—2.30 P.M.: Gynæcological Operations (Dr. Giles). Cliniques:—Medical Out-patient (Dr. Whiting), Surgical Out-patient (Mr. Carson). 3 P.M.: Medical In-patient (Dr. Chappel). 4.30 P.M.: Special Demonstration of Cases of Children's Disease (Dr. T. R. Whipham).

London School of Clinical Medicine (Dreadnought Hospital, Greenwich).—2.30 P.M.: Operations. 2.30 P.M.: Dr. G. Rankin: Medicine. 4.15 P.M.: Sir W. Bennett: Surgery. 4 P.M.: Mr. M. *Davidson: Radiography.* Out-patient Demonstrations:—10 A.M.: Surgical and Medical. 12 noon: Ear and Throat. 3.15 P.M.: Special Lecture:—Sir William Bennett.

Charing Cross Hospital.—4 P.M.: Mr. Waterhouse: Demonstration (Surgical). (Post-Graduate Course.)

Hospital for Sick Children (Gt. Ormond-street, W.C.).—4 P.M.: Lecture:—Mr. Kellock: Affections at and about the Umbilicus.

Royal Institute of Public Health (37, Russell-square, W.C.).—5 P.M.: Special Lecture:—Dr. L. W. Sambon: The Development of Africa: A Problem of Comparative Pathology.

FRIDAY (21st).—Post-Graduate College (West London Hospital, Hammersmith-road, W.).—10 A.M.: Dr. Moullin: Gynæcological Operations. 2 P.M.: Medical and Surgical Clinics. Dr. Ball: Diseases of the Throat, Nose, and Ear. X Rays. 2.30 P.M.: Operations. Dr. Abraham: Diseases of the Skin. 5 P.M.: Lecture:—Dr. Abraham: Cases of Skin Disease.

North-East London Post-Graduate College (Prince of Wales's General Hospital, Tottenham, N.).—9.30 A.M.: Clinique:—Surgical Out-patient (Mr. H. Evans). 2.30 P.M.: Surgical Operations (Mr. Edmunds). Cliniques:—Medical Out-patient (Dr. Auld), Eye (Mr. Brooks). 3 P.M.: Medical In-patient (Dr. Leslie).

Medical Graduates' College and Polyclinic (22, Chenies-street, W.C.).—4 P.M.: Mr. C. A. Parker: Clinique. (Throat.)

London School of Clinical Medicine (Dreadnought Hospital, Greenwich).—2.15 P.M.: Dr. R. Bradford: Medicine. 2.30 P.M.: Operations. 3.15 P.M.: Mr. McGavin: Surgery. Out-patient Demonstrations:—10 A.M.: Surgical and Medical. 12 noon: Skin.

National Hospital for the Paralysed and Epileptic (Queen-square, Bloomsbury, W.C.).—3.30 P.M.: Clinical Lecture:—Dr. A. Turner: Paralysis Agitans.

Central London Throat and Ear Hospital (Gray's Inn-road, W.C.).—3.45 P.M.: Demonstration: Mr. C. Nourse: Larynx.

SATURDAY (22nd).—Post-Graduate College (West London Hospital, Hammersmith-road, W.).—10 A.M.: Dr. Ball: Diseases of the Throat, Nose, and Ear. 2 P.M.: Medical and Surgical Clinics. X Rays. Mr. K. Scott: Diseases of the Eye. 2.30 P.M.: Operations.

London School of Clinical Medicine (Dreadnought Hospital, Greenwich.)—2.30 P.M.: Operations. Out-patient Demonstrations:—10 A.M.: Surgical and Medical. 11 A.M.: Eye.

EDITORIAL NOTICES.

IT is most important that communications relating to the Editorial business of THE LANCET should be addressed *exclusively* "TO THE EDITORS," and not in any case to any gentleman who may be supposed to be connected with the Editorial staff. It is urgently necessary that attention be given to this notice.

It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this office.

Lectures, original articles, and reports should be written on one side of the paper only, AND WHEN ACCOMPANIED BY BLOCKS IT IS REQUESTED THAT THE NAME OF THE AUTHOR, AND IF POSSIBLE OF THE ARTICLE, SHOULD BE WRITTEN ON THE BLOCKS TO FACILITATE IDENTIFICATION.

Letters, whether intended for insertion or for private information, must be authenticated by the names and addresses of their writers—not necessarily for publication.

We cannot prescribe or recommend practitioners.

Local papers containing reports or news paragraphs should be marked and addressed "To the Sub-Editor."

Letters relating to the publication, sale and advertising departments of THE LANCET *should be addressed "To the Manager."*

We cannot undertake to return MSS. not used.

MANAGER'S NOTICES.

TO SUBSCRIBERS.

WILL Subscribers please note that only those subscriptions which are sent direct to the Proprietors of THE LANCET at their Offices, 423, Strand, London, W.C., are dealt with by them? Subscriptions paid to London or to local newsagents (with none of whom have the Proprietors any connexion whatever) do not reach THE LANCET Offices, and consequently inquiries concerning missing copies, &c., should be sent to the Agent to whom the subscription is paid, and *not* to THE LANCET Offices.

Subscribers, by sending their subscriptions direct to THE LANCET Offices, will insure regularity in the despatch of their Journals and an earlier delivery than the majority of Agents are able to effect.

THE COLONIAL AND FOREIGN EDITION (printed on thin paper) is published in time to catch the weekly Friday mails to all parts of the world.

The rates of subscriptions, post free, either from THE LANCET Offices or from Agents, are:—

FOR THE UNITED KINGDOM.		TO THE COLONIES AND ABROAD.	
One Year	£1 12 6	One Year	£1 14 8
Six Months	0 16 3	Six Months	0 17 4
Three Months	0 8 2	Three Months	0 8 8

Subscriptions (which may commence at any time) are payable in advance. Cheques and Post Office Orders (crossed "London and Westminster Bank, Westminster Branch") should be made payable to the Manager, Mr. CHARLES GOOD, THE LANCET Offices, 423, Strand, London, W.C.

TO COLONIAL AND FOREIGN SUBSCRIBERS.

SUBSCRIBERS ABROAD ARE PARTICULARLY REQUESTED TO NOTE THE RATES OF SUBSCRIPTIONS GIVEN ABOVE. It has come to the knowledge of the Manager that in some cases higher rates are being charged, on the plea that the heavy weight of THE LANCET necessitates additional postage above the ordinary rate allowed for in the terms of subscriptions. Any demand for increased rates, on this or on any other ground, should be resisted. The Proprietors of THE LANCET have for many years paid, and continue to pay, the whole of the heavy cost of postage on overweight foreign issues; and Agents are authorised to collect, and generally do so collect, from the Proprietors the cost of such extra postage.

The Manager will be pleased to forward copies direct from the Offices to places abroad at the above rates, whatever be the weight of any of the copies so supplied. Address—THE MANAGER, THE LANCET OFFICES, 423, STRAND, LONDON, ENGLAND.

METEOROLOGICAL READINGS.

(*Taken daily at 8.30 a.m. by Steward's Instruments.*)

During the week marked copies of the following newspapers have been received:—*Ardrossan and Salcoats Herald, Glasgow Weekly Herald, Wellingborough News, Oxford Gazette, Leamington Spa Courier, Midland Evening News, Norwich Press, Weekly Times and Echo, Daily Express, Morning Advertiser, Broad Arrow, Pall Mall Gazette, Ormskirk Advertiser, Hackney Mercury, Plymouth Morning News, Kensington News, Chiswick Times, Essex Times, Hertfordshire Standard, Essex Newsman, Gresham Standard, Oxford Chronicle, &c.*

It appears, however, that Mr. Duncan held a vivisection certificate for some premises at Worcester and under this certificate certain inoculation experiments had been made as regards a suspected case of anthrax in cattle, a suspected case of anthrax in man, and a suspected case of tuberculosis in man. These experiments were all negative, with the exception of the case of suspected anthrax in man, which gave a positive result, and the patient was promptly treated for anthrax, his life being presumably saved thereby. These experiments seem to have filled Viscount Harberton with horror. He now considers that Mr. Duncan is a vivisectionist, and more than that, he considers that Mr. Willis Bund is one also. The class of mind which can take exception to experiments of this kind is extraordinary.

A MEDICAL SCHOOLMASTER.

To the Editors of The Lancet.

Sirs,—I should be glad if you would kindly advise me through your columns with regard to the following case. I have taken down my plate and have advertised in a London paper that I am prepared to take private pupils, giving the nature of my art degree at Cambridge. In support of my competency to look after the physical health of the boys I have said that I am a fully qualified medical man and have mentioned my degrees. Is there anything unprofessional in this or anything that the Medical Council would object to?

I inclose my card and thank you in anticipation.

I am, Sirs, yours faithfully,

June 10th, 1907. M.B.

*** We see nothing unprofessional whatever in our correspondent's action, while there is much to be said in favour of the medical schoolmaster.—Ed. L.

THE BARKER VIBRATOR.

In The Lancet of Sept. 23rd, 1905, we described the Barker vibrator and gave it as our opinion that it was a good and carefully constructed instrument for producing rapid vibration of the tissues. The instrument which we then described was driven by a small motor fixed upon a pedestal. Mr. J. Barker has now brought out his vibrator in a portable form—i.e., the motor together with the applicator weigh about four pounds and so can be easily carried by the medical man to the patient's house. The current is taken from the ordinary mains and the motor can be supplied for either alternating or continuous current. The motor is wound to take a current of 110 volts pressure, and if the current in use is delivered at a higher pressure a lamp resistance is supplied. There is only one disadvantage which the portable motor presents as against the fixed motor, and that is that as it is moved about it is sometimes noisy. But this is a very small disadvantage. The price of the new style of vibrator is £5 5s. and for therapeutical effects it is practically as good as the old style. As we said in our previous report, the vibrator does not appear to be exploited as a cure for every disease, nor are members of the public invited to apply it themselves.

AN IMPROVED COPPER SOLUTION FOR THE ESTIMATION OF SUGAR.

So many modifications of the original method suggested by Fehling for the estimation of sugar have been proposed from time to time that it may seem superfluous to mention another. Still, as we have found that the results were decidedly good and the change from a blue to a colourless solution sharp we may briefly describe a method recently introduced to our notice by Mr. W. Brumwell of 71, Gamage-buildings, Holborn, London, E.C. In this method the use of potassium or sodium tartrate is done away with altogether, ammonia being depended upon for dissolving the suboxide of copper reduced by the grape sugar. The special point about the method, however, is that the double salt of sulphate of ammonia and copper is employed instead of the ordinary sulphate. The reagent is prepared, therefore, with ammonium sulphate, copper sulphate, potassium hydrate, ammonium hydrate, glycerine, and a sufficiency of water so that one cubic centimetre of the reagent is the equivalent of 0·00526 gramme of glucose. The double salt of copper and ammonia may be prepared by adding ammonium hydrate to a solution of copper sulphate until the hydrate precipitated dissolves to a deep blue solution. Alcohol is then added which results in the separation of the double salt of ammonia and copper. The crystals must be used at once as they give off ammonia and basic sulphates form. The solution supplied to us is most convenient to work with and gives accurate results. The change from a blue to a colourless solution is very sharp and can be very readily observed. The results are fairly accurate even when testing a urine containing a small percentage of sugar by adding it to a drachm of the copper reagent drop by drop.

◆

Shoreditch.—The questions are asked in too general terms to make it possible to answer them. If by "private hospital" an institution is meant, before we can give an answer we should require to know the *conditions* under which the private hospital is founded and the regulations governing it. We should also have to see specimens of the "notices" in question.

Pallas.—We know nothing of the quack preparation in question. We do not give advice as to the prevention of child-bearing.

Communications not noticed in our present issue will receive attention in our next.

Medical Diary for the ensuing Week.

OPERATIONS.

METROPOLITAN HOSPITALS.

MONDAY (17th).—London (2 P.M.), St. Bartholomew's (1.30 P.M.), St. Thomas's (3.30 P.M.), St. George's (2 P.M.), St. Mary's (2.30 P.M.), Middlesex (1.30 P.M.), Westminster (2 P.M.), Chelsea (2 P.M.), Samaritan (Gynæcological, by Physicians, 2 P.M.), Soho-square (2 P.M.), City Orthopædic (4 P.M.), Gt. Northern Central (2.30 P.M.), West London (2.30 P.M.), London Throat (9.30 A.M.), Royal Free (2 P.M.), Guy's (1.30 P.M.), Children, Gt. Ormond-street (3 P.M.), St. Mark's (2.30 P.M.).

TUESDAY (18th).—London (2 P.M.), St. Bartholomew's (1.30 P.M.), St. Thomas's (3.30 P.M.), Guy's (1.30 P.M.), Middlesex (1.30 P.M.), Westminster (2 P.M.), West London (2.30 P.M.), University College (2 P.M.), St. George's (1 P.M.), St. Mary's (1 P.M.), St. Mark's (2.30 P.M.), Cancer (2 P.M.), Metropolitan (2.30 P.M.), London Throat (9.30 A.M.), Samaritan (9.30 A.M. and 2.30 P.M.), Throat, Golden-square (9.30 A.M.), Soho-square (2 P.M.), Chelsea (2 P.M.), Central London Throat and Ear (2 P.M.), Children, Gt. Ormond-street (2 P.M., Ophthalmic, 2.15 P.M.), Tottenham (2.30 P.M.).

WEDNESDAY (19th).—St. Bartholomew's (1.30 P.M.), University College (2 P.M.), Royal Free (2 P.M.), Middlesex (1.30 P.M.), Charing Cross (3 P.M.), St. Thomas's (2 P.M.), London (2 P.M.), King's College (2 P.M.), St. George's (Ophthalmic, 1 P.M.), St. Mary's (2 P.M.), National Orthopædic (10 A.M.), St. Peter's (2 P.M.), Samaritan (9.30 A.M. and 2.30 P.M.), Gt. SATURDAY (22nd).—Royal Free (9 A.M.), London (2 P.M.), Middlesex (1.30 P.M.), St. Thomas's (2 P.M.), University College (9.15 A.M.), Charing Cross (2 P.M.), St. George's (1 P.M.), St Mary's (10 P.M.), Throat, Golden-square (9.30 A.M.), Guy's (1.30 P.M.), Children, Gt. Ormond-street (9.30 A.M.).

At the Royal Eye Hospital (2 P.M.), the Royal London Ophthalmic (10 A.M.), the Royal Westminster Ophthalmic (1.30 P.M.), and the Central London Ophthalmic Hospitals operations are performed daily.

SOCIETIES.

TUESDAY (18th).—Medico-Legal Society (22, Albemarle-street, W.).—8.30 P.M.: Exhibition of Medico-Legal Specimens. Discussion on Opinion and Fact in Medical Matters (introduced by Dr. C. H. Wise).

WEDNESDAY (19th).—Royal Meteorological Society (70, Victoria-street, Westminster, S.W.).—4.30 P.M.: Exhibition of "Step" Anemometer by Mr. W. Child. Papers:—Mr. F. C. Bayard: Weather and Crops, 1891–1906.—Mr. C. P. Hooker: The Relation of the Rainfall to the Depth of Water in a Well at Cirencester, 1903–1906.

Royal Microscopical Society (20, Hanover-square, W.).—8 P.M.: Paper:—Mr. E. M. Nelson: Eye-pieces for the Microscope. Lecture:—Mr. F. Enock: The Life-history of the Tiger Beetle (Cicindela campestris) (illustrated by lantern slides).

Royal Medical and Chirurgical Society (20, Hanover-square, W.).—5.30 P.M.: Mr. D'Arcy Power: Dr. Walter Bayley and his Works, 1529–92. (There will also be a number of exhibits of medical and antiquarian interest.)

LECTURES, ADDRESSES, DEMONSTRATIONS, &c.

MONDAY (17th).—Post-Graduate College (West London Hospital, Hammersmith road, W.).—12 noon: Pathological Demonstration:—Dr. Low. 2 P.M.: Medical and Surgical Clinics. X Rays. Mr. Dunn: Diseases of the Eye. 2.30 P.M.: Operations. 5 P.M.: Clinical Lecture:—Mr. Armour.

North-East London Post-Graduate College (Prince of Wales's General Hospital, Tottenham, N.).—Cliniques:—9.30 A.M.: Surgical Out-patient (Mr. H. Evans). 2.30 P.M.: Medical Out-patient (Dr. Whipham); Throat, Nose, and Ear (Mr. Carson); X Ray (Dr. Pirie).

London School of Clinical Medicine (Dreadnought Hospital, Greenwich).—2.15 P.M.: Sir Dyce Duckworth: Medicine. 2.30 P.M.: Operations. 3.15 P.M.: Mr. W. Turner: Surgery. 4 P.M.: Dr. StClair Thomson: Diseases of the Throat, Nose, and Ear. Out-patient Demonstrations:—10 A.M.: Surgical and Medical. 12 noon: Ear and Throat. 4 P.M.: Special Lecture:—Dr. StClair Thomson: Paralysis of the Vocal Cords.

TUESDAY (18th).—Royal College of Physicians of London (Pall Mall East).—5 P.M.: Croonian Lecture:—Dr. W. J. R. Simpson: Plague.

Post-Graduate College (West London Hospital, Hammersmith-road, W.).—10 A.M.: Dr. Moullin: Gynæcological Operations. 2 P.M.: Medical and Surgical Clinics. X Rays. Dr. Ball: Diseases of the Throat, Nose, and Ear. 2.30 P.M.: Operations. Dr. Abraham: Diseases of the Skin.

A Clinical Lecture

ON

THE NATURE AND TREATMENT OF PILES.

Delivered at University College Hospital
on Feb. 27th, 1907,

By ARTHUR E. J. BARKER, F.R.C.S. Eng.,
PROFESSOR OF SURGERY AT UNIVERSITY COLLEGE HOSPITAL SCHOOL AND SURGEON TO THE HOSPITAL.

GENTLEMEN,—A number of cases of piles having recently been under my care in the wards and outside the hospital has suggested that the subject of the nature and treatment of hæmorrhoids would be a suitable one for a practical clinical lecture while the cases you have seen are fresh in your memories.

But first, what is a pile? This question is not a difficult one to answer. A pile is primarily a dilated or varicose condition of one or more of the plexus of veins lying under the mucous membrane of the last inch or so of the lower bowel. Probably there is a congenital weakness of the muscular coat of these veins in most cases, just as we find the same thing in the case of the veins of the leg. If we inquire of patients suffering from hæmorrhoids we constantly hear that their parents were similarly afflicted or other members of the same family and a considerable number of them have developed the trouble early in life. But this is not all. There are other factors in the production of piles. These divide themselves into two groups: first, any cause of obstruction to the return of blood through the inferior hæmorrhoidal plexus; and, secondly, any cause of local irritation. In the first group come a sluggish liver with engorgement of all the veins of the portal system, heart disease, pregnancy, and ovarian cysts and other pelvic tumours, and, most common of all, a loaded bowel in chronic constipation, and prolonged standing or sitting. In the second come every kind of septic irritation, the commonest being want of cleanliness after defæcation; then local mechanical irritation, such as chafing, bumping on rough roads, sitting on damp seats, &c.

It is easy to understand how the factors in the first group act upon veins congenitally weaker walled than usual. They become simply more and more distended as their weak walls yield to the strain from above. But at first sight it is not quite so easy to explain how local irritation plays a part in their production. And yet a little thought makes the matter plain. Local irritation prolonged for any time leads to hyperæmia and in the end to inflammation of a chronic type, with gradual loss of tone in the walls of the vessels in the inflamed area and their gradual dilatation by the stress from within. This inflammation has also other effects. It may lead to clotting in the veins, with or without suppuration, and it may cause chronic thickening in the tissues around which may become permanent. Piles formed in any of these ways, alone or combined, only exist in the lowest part of the rectum in or about the anus—the "pile-bearing area" of Whitehead. They may come to lie quite internal to the anal sphincter or external to it, or sometimes one, sometimes the other, when they are called intermediate. They may be spongy owing to great vascularity, or hard from periphlebitis, or clotted and inflamed from a more acute inflammation.

As a rule most patients who consult us for piles have been suffering from them for a long time. A variety of causes have been at work but most usually perhaps want of cleanliness and lack of attention to the emptying of the bowels. But as a rule they only come to us surgeons at a time when they think that nothing but an operation will relieve them. And this brings us to the question of treatment.

Now the first point I want you to understand is this, that many cases of piles even when very large do not require operation for their cure. Of course, some are beyond the reach of any other treatment short of operation. Again, you will do well to remember that many cases of very large piles which will ultimately require operation are not when you first see them in a safe state for operative treatment. By this is meant that in many cases as they come to you there is much septic irritation about the anus and rectum from want of cleanliness. On the one hand, this is keeping up congestion and dilatation of the veins, and on the other any operation undertaken at this time would be attended with risk from dislodgement of clots and further would not be followed by that union without suppuration which is necessary if contraction of the anus is to be avoided. These points cannot be insisted on too much or too frequently.

The first thing, then, in any case of piles is to see that they are relieved from any source of engorgement from within by gentle laxatives and bodily exercise and that the local condition be patiently treated on antiseptic principles. The piles and surrounding parts should be washed over three times daily, while the patient brings them into prominence by straining. The first washing should be done with soap and water and it may be said of this that if it were employed night and morning by those who suffer from pruritus and a slight tendency to hæmorrhoids there would be far fewer cases which needed operation. Not only is this treatment preventive of piles but when they are undoubtedly present they will become much smaller and even disappear when it is carried out patiently and regularly. But when piles are present in abundance and covered by irritating mucous discharge as a rule antiseptics are used with advantage if not too powerful. Perhaps the best of all is bichloride of mercury, 1 part in 1000; at least, I have found it so. After the first washing of the piles with soap and water they are gently bathed with this lotion by means of a piece of gauze, old linen, or wool steeped in lotion. If possible they should then be reduced within the anus but without force, and the patient should where convenient lie down for a little time afterwards. This should be done in the morning after the bowels have been relieved and at night before going to bed. It is surprising what improvement will take place even in very bad cases under this treatment. Over and over again I have seen large crops of piles disappear completely and patients who were miserable before and who had made up their minds to operation have been able to postpone the latter indefinitely. But even suppose that hæmorrhoids are not quite cured in this way the improvement in their condition under this treatment is usually so great that when an operation comes to be done the prospects of its success are much improved. Indeed, wherever practicable I have always insisted that this treatment should precede any operative undertaking. It must not be forgotten that any inflammatory condition round a vein in any part of the body is not devoid of risk. Such conditions not infrequently are followed by thrombosis and embolism with all their well-known dangers. And in the neighbourhood of the anus, where such a thrombosis is almost sure to become septic, this danger must always be kept in mind and all rough handling of an inflamed pile be avoided. But besides this danger there is also that of operation on an area in which inflamed veins lie. Not only is there very little prospect of satisfactory union of a wound where such a condition exists but there is also the danger of dislodging septic thrombi and also septic absorption from the wound. In all cases, therefore, you will do well to wait until such treatment as that just described has brought about a subsidence of all inflammation before any operation on this region is attempted. The only exception to this rule is, perhaps, that of the single suppurating external pile which after being carefully cleansed with antiseptics may be slit across in the long axis of the bowel and its contents evacuated just as an abscess would be emptied elsewhere. But this should be done with care and by no means treated lightly.

How are we now going to deal with well-marked piles which have resisted the treatment indicated above? In the first place, we will suppose the case of a single large one protruding from the margin of the anus. The older method of simply tying a ligature round its base and allowing it to slough off may be rejected at once as painful and not without risk as the separation of the strangled mass cannot take place without septic suppuration which, for reasons given, is dangerous. Of course, the base of the pile can be clamped in the long axis of the bowel and burned through with a cautery knife. This gives an aseptic surface to begin with, but one which is sure to be fouled later, and when it granulates up there may be more contraction of the anus at the spot than is comfortable, although, as the line of shrinking is in the long axis of the bowel, it is not as a rule excessive. But the best mode of dealing with a solitary pile where the rest of the anus is healthy is based on the conclusion that with great care a wound in this region can be induced to heal by first intention as

A Clinical Lecture

ON

THE NATURE AND TREATMENT OF PILES.

Delivered at University College Hospital
on Feb. 27th, 1907,

BY ARTHUR E. J. BARKER, F.R.C.S. ENG.,
PROFESSOR OF SURGERY AT UNIVERSITY COLLEGE HOSPITAL SCHOOL
AND SURGEON TO THE HOSPITAL.

GENTLEMEN,—A number of cases of piles having recently been under my care in the wards and outside the hospital has suggested that the subject of the nature and treatment of hæmorrhoids would be a suitable one for a practical clinical lecture while the cases you have seen are fresh in your memories.

But first, what is a pile? This question is not a difficult one to answer. A pile is primarily a dilated or varicose condition of one or more of the plexus of veins lying under the mucous membrane of the last inch or so of the lower bowel. Probably there is a congenital weakness of the muscular coat of these veins in most cases, just as we find the same thing in the case of the veins of the leg. If we inquire of patients suffering from hæmorrhoids we constantly hear that their parents were similarly afflicted or other members of the same family and a considerable number of them have developed the trouble early in life. But this is not all. There are other factors in the production of piles. These divide themselves into two groups: first, any cause of obstruction to the return of blood through the inferior hæmorrhoidal plexus; and, secondly, any cause of local irritation. In the first group come a sluggish liver with engorgement of all the veins of the portal system, heart disease, pregnancy, and ovarian cysts and other pelvic tumours, and, most common of all, a loaded bowel in chronic constipation, and prolonged standing or sitting. In the second come every kind of septic irritation, the commonest being want of cleanliness after defæcation; then local mechanical irritation, such as chafing, bumping on rough roads, sitting on damp seats, &c.

It is easy to understand how the factors in the first group act upon veins congenitally weaker walled than usual. They become simply more and more distended as their weak walls yield to the strain from above. But at first sight it is not quite so easy to explain how local irritation plays a part in their production. And yet a little thought makes the matter plain. Local irritation prolonged for any time leads to hyperæmia and in the end to inflammation of a chronic type, with gradual loss of tone in the walls of the vessels in the inflamed area and their gradual dilatation by the stress from within. This inflammation has also other effects. It may lead to clotting in the veins, with or without suppuration, and it may cause chronic thickening in the tissues around which may become permanent. Piles formed in any of these ways, alone or combined, only exist in the lowest part of the rectum in or about the anus—the "pile-bearing area" of Whitehead. They may come to lie quite internal to the anal sphincter or external to it, or sometimes one, sometimes the other, when they are called intermediate. They may be spongy owing to great vascularity, or hard from periphlebitis, or clotted and inflamed from a more acute inflammation.

As a rule most patients who consult us for piles have been suffering from them for a long time. A variety of causes have been at work but most usually perhaps want of cleanliness and lack of attention to the emptying of the bowels. But as a rule they only come to us surgeons at a time when they think that nothing but an operation will relieve them. And this brings us to the question of treatment.

Now the first point I want you to understand is this, that many cases of piles even when very large do not require operation for their cure. Of course, some are beyond the reach of any other treatment short of operation. Again, you will do well to remember that many cases of very large piles which will ultimately require operation are not when you first see them in a safe state for operative treatment. By this is meant that in many cases as they come to you there is much septic irritation about the anus and rectum from want of cleanliness. On the one hand, this is keeping up congestion and dilatation of the veins, and on the other any operation undertaken at this time would be attended with risk from dislodgement of clots and further would not be followed by that union without suppuration which is necessary if contraction of the anus is to be avoided. These points cannot be insisted on too much or too frequently.

The first thing, then, in any case of piles is to see that they are relieved from any source of engorgement from within by gentle laxatives and bodily exercise and that the local condition be patiently treated on antiseptic principles. The piles and surrounding parts should be washed over three times daily, while the patient brings them into prominence by straining. The first washing should be done with soap and water and it may be said of this that if it were employed night and morning by those who suffer from pruritus and a slight tendency to hæmorrhoids there would be far fewer cases which needed operation. Not only is this treatment preventive of piles but when they are undoubtedly present they will become much smaller and even disappear when it is carried out patiently and regularly. But when piles are present in abundance and covered by irritating mucous discharge as a rule antiseptics are used with advantage if not too powerful. Perhaps the best of all is bichloride of mercury, 1 part in 1000; at least, I have found it so. After the first washing of the piles with soap and water they are gently bathed with this lotion by means of a piece of gauze, old linen, or wool steeped in lotion. If possible they should then be reduced within the anus but without force, and the patient should where convenient lie down for a little time afterwards. This should be done in the morning after the bowels have been relieved and at night before going to bed. It is surprising what improvement will take place even in very bad cases under this treatment. Over and over again I have seen large crops of piles disappear completely and patients who were miserable before and who had made up their minds to operation have been able to postpone the latter indefinitely. But even suppose that hæmorrhoids are not quite cured in this way the improvement in their condition under this treatment is usually so great that when an operation comes to be done the prospects of its success are much improved. Indeed, wherever practicable I have always insisted that this treatment should precede any operative undertaking. It must not be forgotten that any inflammatory condition round a vein in any part of the body is not devoid of risk. Such conditions not infrequently are followed by thrombosis and embolism with all their well-known dangers. And in the neighbourhood of the anus, where such a thrombosis is almost sure to become septic, this danger must always be kept in mind and all rough handling of an inflamed pile be avoided. But besides this danger there is also that of operation on an area in which inflamed veins lie. Not only is there very little prospect of satisfactory union of a wound where such a condition exists but there is also the danger of dislodging septic thrombi and also septic absorption from the wound. In all cases, therefore, you will do well to wait until such treatment as that just described has brought about a subsidence of all inflammation before any operation on this region is attempted. The only exception to this rule is, perhaps, that of the single suppurating external pile which after being carefully cleansed with antiseptics may be slit across in the long axis of the bowel and its contents evacuated just as an abscess would be emptied elsewhere. But this should be done with care and by no means treated lightly.

How are we now going to deal with well-marked piles which have resisted the treatment indicated above? In the first place, we will suppose the case of a single large one protruding from the margin of the anus. The older method of simply tying a ligature round its base and allowing it to slough off may be rejected at once as painful and not without risk as the separation of the strangled mass cannot take place without septic suppuration which, for reasons given, is dangerous. Of course, the base of the pile can be clamped in the long axis of the bowel and burned through with a cautery knife. This gives an aseptic surface to begin with, but one which is sure to be fouled later, and when it granulates up there may be more contraction of the anus at the spot than is comfortable, although, as the line of shrinking is in the long axis of the bowel, it is not as a rule excessive. But the best mode of dealing with a solitary pile where the rest of the anus is healthy is based on the conclusion that with great care a wound in this region can be induced to heal by first intention as perfectly as in any other part of the body. There is a general belief that because this is the channel by which the system is relieved of its solid impurities it cannot be expected that wounds in or about the anus can heal as aseptic wounds in other parts do. But this is not so. It is all a question of preliminary treatment. And here again some old traditions still exist. The practice hitherto in preparing a patient for a pile operation has *often* been to give a dose of some strong laxative, such as castor oil, the day before operation and an enema a few hours before. The consequence of this practice is too often that at the moment of relaxation of the anus by the anæsthetic or in the course of the operation a quantity of loose motion is discharged which seriously imperils the chances of primary union. This is a wrong course to pursue as to the time of preparation. When we wish thoroughly to clear out the bowel we should begin much earlier. The laxative should be given three or four days *before operation for* two days in succession, assisted if necessary by enemata or as *often* as is found indispensable to unload the colon and secure liquid motions free of old stagnant fæces. After this the bowels should be left in a state of rest for at least 24 hours before operation. By these measures we secure an empty bowel free of mucus and less engorged with blood than if it were in a state of action. It can consequently be cleansed and remain clean during the operation.

Another point which is essential for a proper control of the anus during operation is that it should be perfectly relaxed. This is to a certain extent secured by the general anæsthesia employed but not adequately. For this reason it is well in all cases to stretch the sphincter with the thumbs. First one thumb is inserted into the anus, then the other alongside of the first, and then with the fingers spread out on the nates on both sides by making the movement of closing the hands the thumbs are separated slowly and steadily from one another and the sphincter is thus steadily stretched without any sudden pull which might overdo the distension. If spinal analgesia is employed this stretching is unnecessary, as the sphincter is thoroughly relaxed, with loss of sensation at the same time. In either case the pile or piles project with the mucous membrane of the bowel and all the parts around can be cleansed with antiseptics and finally by a flush of sterile saline solution. But before the operation is begun it is well *to stuff the rectum with a wisp of sterile gauze to prevent* any mucus or motion from coming down during the procedure. To remove a single pile under these conditions is now easy. It is simply drawn forward with suitable pile forceps and its base is included between two elliptical incisions in the long axis of the bowel.' These incisions should only divide the mucous membrane and define the root in which run the vessels. This root is now surrounded with a fine thread and tied tightly and the pile is snipped off with a scissors outside the ligature. The mucous membrane is then closed over the stump and the whole area is dusted with iodoform. After this, and only after the dusting, the wisp of gauze is removed from the rectum. Then a pad of iodoform gauze secured by a T bandage is placed over the anus. Such an operation ought to be, and is, followed by *primary union* if done cleanly, and there is not the least damage to the functions of the anus.

But there are other cases in which the whole of the inferior hæmorrhoidal plexus is involved and there *is a more* or less complete *ring of piles round the anus*. Here we may proceed if we like upon the same lines as above and remove each pile separately. But if we do so we must be prepared to find that the amount of mucous membrane is somewhat too little to cover all the stumps and there *is some risk of* contraction of the anus if we have granulating surfaces left. For my own part, I believe that in such cases there is no better operation than that known as Whitehead's. But then it must be done on the lines which were so well laid down by this surgeon many years ago. The objections which have been raised to it from time to time are based upon conclusions from operations which in many cases have been done without due regard to the principles laid down by the originator of the operation. Whitehead started from the fact that in a case where the anus was encircled by a ring of piles the whole practically of that part of the inferior hæmorrhoidal plexus lying within an inch or so of the margin of the anus was involved in the varicose condition. From this he argued that no operation could be considered complete which did not remove the whole of this plexus. By the removal of this not only would the condition present be removed but also the chance of any return of piles, inasmuch as the plexus from which they always spring had been completely taken away. To effect this he proceeded as follows: after the bowel had been unloaded as above described and cleansed by thorough washing, in order to gain complete access to the "pile-bearing" area the sphincter ani was first stretched as above described until quite relaxed. The consequence of this should be, and is if rightly done, that there is a prolapse of the mucous membrane of the lower inch of the rectum. When this has again been thoroughly cleansed the forefinger of the left hand is inserted into the anus and between it and the thumb the anterior part of the prolapse is drawn down. Then at a point in front where the purple skin of the anus proper merges into the skin around a short transverse slit is made between the two with curved scissors at the most anterior part of the anus. Into this slit the blunt point of the scissors is inserted under the skin and forced outwards first on one side and then on the other until about half an inch has been undermined. This is then evenly cut away and the scissors are thrust again under a fresh portion of skin which is similarly cut until the whole circumference of the purple skin has been separated from the true skin around the anus. If the right depth has been cut off this is quite easy and is only followed by very trifling bleeding. Holding the ring of piles now separated from the skin of the anus in a series of pile forceps and drawing gently on the whole tube of mucous membrane it is now easy with an elevator, or, better still, with closed blunt-ended scissors, to push back, as it were, the external *sphincter ani*, which is well seen, until all round the anus it is separated from the tube of mucous membrane for about one inch. This tube, containing all the piles and "pile-bearing" area, consists not alone of mucous membrane but of submucous tissue, veins, and a thicker layer of condensed fibrous tissue which separates it from the external sphincter. If the stripping takes place accurately between it and the sphincter, as should always be the case, it is particularly easy and very little blood is lost. If the beginner dissects in the muscle on the one hand, or among the veins on the other, there is much oozing, but a little experience will enable the surgeon to work at the proper depth.

The tube of pile-bearing area being now drawn down for about an inch to one and a half inches is snipped through for about half an inch transversely at a point at which when lifted up the divided edge reaches to the cut skin. The edge so produced is stitched to the corresponding edge of the skin accurately, any vessel which may have been divided being included in the ligature. It is not worth while to stop *to tie it* separately. In placing *these stitches* and all those which follow them it is well to include a good depth of mucous and the sub-mucous tissues to obtain a good hold for the threads. When all is secure here further snips are successively made, continuing the first *on both* sides transversely from before backwards. But as each is made the cut tube is stitched to the skin at once as before previously to making the next snip. In this way hæmorrhage is avoided and the tube is cut away more evenly at the same level and when the last few snips only remain we see the new anal margin almost completed with little or no bleeding. The last transverse snip and attachment of the cut edge to the skin posteriorly finish the procedure, an entire ring of piles having been taken away *with the plexus of veins* to which they belonged. The appearance of the anus is then nearly normal. The healthy mucous membrane brought down from above is seen attached evenly to the skin of the margin over *the sphincter* which has not been injured in any way. As the sphincter will *remain* weak after having been stretched usually for some days the mucous membrane is more evident for that time, but as the muscle recovers power it is drawn inwards to its usual height unless too much skin externally has been removed, *when it forms* a moist ring for some time after healing has been completed. But this is only a transient condition, the mucous membrane external to the opening of the anus being before long hardened into the same texture as the original *marginal* skin of the opening and ceasing to secrete.

When the stitching has been completed the parts are dusted with iodoform, the gauze plug *is removed* from the rectum and a morphine *suppository* is introduced. A pad of gauze over the anus is all that is now needed. The after-treatment consists in keeping the part clean with a little boric lotion daily or, better, 1 to 1000 bichloride solution, followed by dusting with *iodoform*. The fine stitches may be left to themselves. They include but a small amount of tissue and are tied in the long axis of the rectum and cut their way out without any trouble. On or about the sixth day an oil enema is given and allowed to remain as long as possible. If it comes away after a few hours it brings away softened fæces. If not a soap-and-water enema is given on the next day. After each motion the anus is washed and dusted as before.

Objections have been raised to this operation here and there but to me they seem groundless. It is urged that there is a risk of suppuration round the stitched ring and consequent contraction. This I can honestly say I have never yet seen, though I have operated in many scores if not hundreds of cases by this method. The objection arises in the minds of those who can hardly believe in an aseptic operation about the anus. But with proper preparation this can be easily accomplished. And during the operation if the dissection is carried out with clean boiled instruments rather than with the fingers there is no reason why the wounded surfaces should not remain aseptic. As a matter of fact, which some of you can vouch for as having seen these cases, the healing is faultless. Another objection which is raised is that the mucous membrane remains moist and painful if it projects over the edge of the anus. If it does project it is due to the fact that too much of the true skin has been removed and the mucous membrane has had to be drawn out to meet it. It is easy to avoid this in the first place, but if it is after healing too low down it is soon converted into normal marginal tissue and gives little trouble in the meantime if washed twice daily with the bichloride solution.

Of all the various operations which I have done or seen done this particular one recommends itself to me above all in cases of advanced piles. And among the very large number of patients I have operated upon in hospital and private none have been dissatisfied with the result. But from the way it is described in some standard works it is plain that the principles and details of Mr. Whitehead have not been clearly appreciated and that operations have been wrongly done. One great merit it certainly has which is not possessed by other methods—i.e., that all tendency to future piles is prevented.

A Clinical Lecture

ON

THE TREATMENT OF HYSTERIA.

Delivered at the West End Hospital for Diseases of the Nervous System,

BY THOMAS D. SAVILL, M.D. LOND.,

PHYSICIAN TO THE HOSPITAL.

GENTLEMEN,—The rational treatment of hysteria must depend upon the application of the principles of pathology and etiology. These I have already discussed on several occasions.[1] Many authors regard hysteria as a psychosis pure and simple and most authors regard its essence as a psychosis which is attended by physical manifestations. I cannot entirely agree with either of these views. Undoubtedly emotional instability is a characteristic of hysterical subjects, but this is only a part, the mental part, of a more widespread instability. A prolonged study of the disorder under somewhat exceptional opportunities has led me to conclude (1) that hysteria consists of an instability or undue irritability of all the nervous and reflex centres throughout the body, and particularly those of the vaso-motor and sympathetic systems; (2) that hysterical paralysis or tremor and many other hysterical phenomena hitherto unexplained are produced by vascular changes in the nervous system or elsewhere; and (3) that the essential defect in the nervous system upon which hysteria depends, whatever it may be, is inborn and inherent—that is to say, the reflex centres in hysterical subjects are throughout life more unstable than those of other people. Many intercurrent or accidental causes have been recognised of late years as capable of determining hysterical manifestations—causes which do not determine hysterical outbreaks in non-hysterical people simply because the reflex centres of the latter are more stable—such as fear, grief, religious exercises, shocks, injuries, all debilitating conditions, pregnancy, parturition, sexual excess, overwork, worry, anæmia, various acute and chronic intoxications such as alcohol, syphilis, lead, rheumatism, diabetes, typhoid fever, influenza, and other specific fevers.[2] There are other causes, not so well recognised, to which I shall direct your attention to-day.

The remarks I have to make on the treatment of hysteria will come under five headings—(*a*) certain general measures directed to improve the tone and nutrition of the nervous system and to allay its irritability; (*b*) other symptomatic treatment, mainly by the aid of drugs; (*c*) etiological treatment which depends on the discovery and eradication of the determining cause of the hysterical manifestation in operation; (*d*) the use of vaso-constrictors, vaso dilators, and blood remedies; and (*e*) educational and other preventive measures.

(*a*) The general measures directed to the improvement of the nervous irritability may consist of rest, isolation from home surroundings, food, massage, electricity, hydrotherapy, and psychotherapy or hypnotism.

1. Of all methods of treatment rest is of the greatest value in allaying any irritability of the nervous system—rest of mind and rest of body. All sources of peripheral irritation must be removed from the body and all sources of worry or anxiety from the mind. Subjects demanding the smallest exercise of the judgment must be excluded. Complete rest of the body can only be obtained in bed, and the patient should not be allowed to sit up or to take any movement that can be avoided. A method of treatment involving complete rest has been carefully elaborated by Mrs. William Archer. The patient is gradually educated to relax completely all the muscles and to direct the mental attention to the relaxation of the muscles, practices which are much more difficult than would at first sight appear. Abundance of sleep is indispensable to hysterical patients, whether as a preventive or remedial agent, and it is sometimes justifiable to administer hypnotic remedies under due precautions.

2. Removal from the conditions under which the disease arose is almost as important as rest, for it not only relieves the patients at once from the worries incidental to their surroundings but it attracts their attention into new channels and away from their disorder. To establish complete isolation of the patient from her previous surroundings it is necessary in many cases not only to remove the patients from home but to forbid any letters to be written or received and to prohibit all visitors or communications with friends. A difficulty often arises in this connexion with the friends and relations who wish to continue their sympathetic manifestations and may not like to surrender the charge of the patient into the hands of strangers. It may, however, be diplomatically explained to them that this is done not from any doubt about the value of their ministrations but simply to place the patient under conditions which differ from those under which the disorder arose. A daily report of the progress can be sent by the nurse or medical attendant.

3. As much easily assimilable food as the patient can take improves the nutrition of the nervous system and of the body generally, and in order to increase the power of assimilation this increased quantity of food may be associated with (4) general massage. The combination of these four measures —rest, isolation, abundance of food, and massage—constitute the system of treatment first adopted by the late Professor J. M. Charcot at the Salpêtrière and afterwards known as the Weir-Mitchell treatment. The details of this treatment are too well known to need description. General massage is given daily with a double object—to soothe the nervous system (by the stroking movements) and to promote the tissue changes and the nutrition of the body (by kneading and other movements). Tapotement is a procedure I do not recommend. Half an hour of massage may be gradually increased to one hour twice daily. The patient should have a glass of warm milk and be instructed not to speak or move a muscle for an hour after each sitting. As a rule no drugs should be given except an occasional aperient or dose of bromide for sleeplessness.

It is not every case of hysteria which is suitable for treatment by the Charcot-Weir-Mitchell methods, and these should never be adopted until skilled medical advice has been obtained, and only when they can be carried out under skilled medical supervision. Without these conditions serious harm may result to the patient and discredit be brought upon a valuable means of treatment. It is important to satisfy oneself by a very thorough examination as to the absence of all organic disease and that no toxic, septic, or organic cause is in operation; it is also of importance that the digestive organs should be in good order. The most suitable cases are: (1) those where the nutrition is below par; (2) those which are purely of nervous origin; and (3) those in which there is considerable irritability of the neuro-muscular system, as evidenced by twitchings and increase of the superficial and deep muscular reflexes. Persistent gloom and despondency are relatively rare in hysteria (excepting in the male), but such cases are wholly unsuitable for this treatment, and I have seen considerable harm done thereby. Cases presenting mental aberration of any kind require considerable caution.

---

[1] THE LANCET, July 20th, 1901, p. 119, and Jan. 30th, 1904, p. 273; Clinical Journal, Dec. 1st, 1897, May 25th and June 1st, 1904.

[2] Georges Guinon: Les Agents Provocateurs de l'Hysterie. Delahaye et Lecrosnier, Paris, 1889.

It is not always necessary to employ all these methods. The case of a young married woman, whom I recently saw with Mr. R. Mortimer Johnson of Balham, illustrates the value of rest alone. She was suffering from hysterical hip-joint disease and after about one month's treatment of complete rest she has recovered. Moreover, the four measures named may be combined in varying proportions.

Here is a patient who illustrates the value of rest, isolation, abundant food, and systematised exercises.

CASE 1.—A girl, aged 17 years, came to the hospital as an out-patient under Dr. E. D. Macnamara, who has kindly allowed me to show the case, in June, 1906, for her third attack of aphonia, each of the attacks having come on suddenly and having been promptly cured by the application of faradism to the larynx. There is a long history of various hysterical manifestations, and for the last two years she has been losing the use first of one limb, then of another. She was brought again on Oct. 3rd for an attack of clonic spasms and weakness chiefly in the right arm, right leg, and left side of the face, which had come on quite suddenly in church a few days previously. The spasms were of considerable violence, and though they were choreiform in character they were somewhat more rhythmical than the chorea of Sydenham. She was at once placed in hospital under a treatment of rest, isolation from her relatives, and abundance of milk (without massage) and you will see now at the end of four weeks that she is perfectly well. There are no movements, no paralysis, and she has gained in weight. Latterly she has had systematised educational movements of the affected limbs, which is a measure I have found of great use in hysterical muscular affections.

5. Electricity is of considerable use, especially in cases which do not need, or cannot undertake, the more exacting forms of treatment just referred to. Galvanic and faradic current electricity is, I believe, very useful for hysterical affections of the voluntary muscles. The constant current is more useful for rigidities, the faradic for paralytic conditions, and you will remember how promptly this last-named form of electricity cured the aphonia in the case you have just seen. Static electricity seems to me to combine three effects. It undoubtedly produces a psychic effect upon the patient; it also seems to improve their general tone; and lastly, it appears to be of special value in cases of anæsthesia when used by the method of sparking. The case of hystero-traumatic paralysis to which I have previously referred[3] was an illustration of this. After three applications of static sparks to the arm which had been completely paralysed and anæsthetic for two months the anæsthesia immediately diminished in area, and after a few more sittings entirely disappeared. The most modern form of electricity in medicine is the high-frequency current and I have used it extensively in various nervous affections. It has appeared to me to do a great deal of good in some cases of hysteria, but the results have been too uncertain and too much confused by other and associated methods of treatment for me to speak with absolute certainty about the value of this form of electricity. It undoubtedly acts as a general tonic, probably by its effects upon the involuntary muscular tissue, more especially of the arteries, both in hysterical and other cases.

6. Hydrotherapy was extensively used by Charcot and others in France in former times with good result, but it has not been much employed in England. Undoubtedly cold or hot water applied to the surface of the body either by douches or baths acts powerfully on the neuro-vascular system and I have seen cases where the shock of a cold douche has not only acted as a powerful tonic but has involved the disappearance of hysterical manifestations. A previous attack in the patient you have seen to-day was suddenly cured by a wet pack. I have seen other cases where the efficacy of hot baths in calming an excited nervous system was very apparent; cases of muscular spasm are generally more amenable to heat than to cold.

7. Under psychotherapy may be included all kinds of persuasion, suggestion (auto- and hetero-) and hypnotism. These methods are not only useful in the slighter cases of uncomplicated hysteria but they sometimes form valuable adjuncts to the other methods just mentioned. It is here where the influence of the physician's personality or character over his patient and the confidence of the latter in the former play a leading rôle. The object of psychotherapy is to cultivate the will and the control of the patient over her unruly emotions and unstable reflex centres. She must be encouraged by firm but gentle methods in the belief that her excitement, paralysis, attacks or what not, can in some degree be controlled, and that each victory, however momentary, leads her to fresh victories hereafter. In the case of paralysis the patient may be taught to realise that the lost movements, or more correctly the ideo-motor centres, can be re-educated. I remember one male patient with a paralysed arm whom I induced to practise daily with a dynamometer, which he watched as it recorded the daily increasing indications of his returning strength. Another patient, a woman with paraplegia, I induced to take a step or two every two hours, and to interest herself in her rapidly improving power of walking.

Hypnotism, throwing a person into an artificial sleep in which he or she is susceptible of suggestion from others, undoubtedly finds a place in the treatment of hysteria, but unfortunately a good many hysterical patients are not hypnotisable. Auto-suggestion, the persuasion of self that one is really almost or quite well, is also of great value. The influence of a person's mind over his body has been recognised in our profession almost from time immemorial and those interested in the subject should read the treatise of the late Dr. Hack Tuke.[4] By suggesting to herself with sufficient force and sufficient frequency that she *is* well and free from pain, a patient may *become* well by the influence of the will over the bodily sensations—in the absence of serious organic disease. This principle forms the basis of several of the modern "cults" or "religions."[5] The potency of the will over the bodily sensations is beyond dispute and, with certain reservations to be mentioned shortly, is a valuable agent in the treatment of hysteria.

(*b*) Other symptomatic treatment mainly with the aid of drugs. First in regard to sedatives. The bromides still remain our sheet anchor for allaying the irritability of the reflex centres, and I prefer ammonium bromide to the other halogen salts. In my experience it may be given for a considerable time, even for years, without any detrimental effect, though it may have the disadvantage of hiding some curable causal condition upon which the hysterical manifestation depends. If the patient complains that she "lives on bromide and cannot do without it," this indicates that some chronic irritation is going on which must be removed. Opium and all its alkaloids are, as a rule, prohibited, not only for fear of the habit but because they do not invariably act as sedatives to these subjects, and because during the reaction phase the patient is generally worse than ever. Apomorphine hypodermically is, however, the most valuable remedy we have for the prompt cure of severe and recurrent hysterical convulsions; it produces copious emesis and the storm clears up like magic. Alcoholic stimulants are forbidden, partly because of the habit so easily engendered, but chiefly, at least in my experience, because alcohol is of itself capable of acting as a determining cause for hysterical storms. Valerian and asafœtida are still the most valuable stimulants we possess for the faintings, prostration, or collapse. The taste of these drugs is not as unpleasant as their odour, which may be partially counteracted by holding the nose while swallowing the medicine. Many attempts have been made to make these drugs more palatable and a partial success has been obtained in borneol isovalerianate.

(*c*) Without detracting from the foregoing methods of treatment which have been in vogue for a number of years there are others which have not yet been sufficiently recognised but which are of equal if not greater importance. The foregoing methods treat the disordered nervous system only; they are more or less empirical. Those to which I now propose to refer depend upon a careful study of the accidental or determining causes of a hysterical manifestation and are based on a thorough investigation of the physiological functions of hysterical patients from the point of view of general medicine and pathology. Having come to the conclusion that the chief seat of the reflex instability lay in the sympathetic vaso-motor systems, it occurred to me that nothing would be more likely to influence these centres than the condition of the blood. I therefore determined to look out for, and if possible correct, any derangement of metabolism, blood alteration, or constitutional disorder which might be in operation. And in confirmation of the view that blood alterations of this kind may determine hysterical outbreaks I have found that quite a considerable number of hysterical patients exhibit dermatographia, erythematous mottling, pruritus, twitchings of the limbs at night, general neuro-muscular irritability, or other symptoms suggestive of toxæmia. Moreover, I have also seen several cases where the hysterical paroxysms have been associated with paroxysms of urticaria, an undoubted toxo-angio-neurosis. Here, for instance, is one of these.

---

CASE 2.—A female, aged 20 years, came to the out-patient department in June, 1905, for curious nervous attacks in which she lost all control over herself and behaved like a mad woman. These began with a feeling of fulness of the head which spread over the body and limbs, after which she "did strange things," and finally became completely collapsed. During these attacks the skin became very red. They were followed by "nettle-rash," which lasted a day or two after. Pressure in the right ovarian region produced the epigastric aura and the commencement of an attack in which one could see the flushing of the skin. Her teeth and digestion were very defective and I prescribed cascara, arsenic, bromide, and alkaline carbonates. She has improved considerably but still gets attacks in which both the nervous and the skin symptoms are less severe. Please notice that the nervous paroxysms and the skin symptoms appeared and disappeared together.

Here are some of the blood conditions (toxæmias) which may be in operation:—

1. It has long been known that various microbic toxins may act as determining causes of hysterical manifestations—such toxins as phthisis, syphilis, typhoid fever, scarlet fever, acute articular rheumatism, pneumonia, &c.[6]

2. It has also been recognised that alcohol, lead, mercury, sulphide of carbon, and other metallic and organic poisons may act similarly.[7]

3. Anæmia is very frequently met with in hysterical girls and when this is remedied the nervous symptoms sometimes cease. Here, for instance, is a girl, aged 20 years, who came to me three months ago suffering from troublesome hysterical attacks. She has been continuously treated by iron and the attacks have quite ceased, though all the other conditions and her home surroundings have remained the same. It is interesting to note that Professor H. Oppenheim,[8] who regards hysteria as a psychosis, points out as a fallacy in the diagnosis of anæmia in hysterical subjects that "the pallor of nervous individuals is not always a sign of anæmia but may be due to vascular spasm"—a statement which I can fully endorse.

4. Various debilitating conditions due to bad or insufficient air or food, with consequent alterations in the blood and the nutrition of the body, are also known to be conditions which may determine hysterical symptoms. And it may be practically useful to advise subjects liable to hysterical or nervous manifestations to keep records of their weight and to consult their medical man when this is falling.

5. All the foregoing are now matters of common knowledge, but it is not yet recognised what an important part gastro-intestinal derangements may play in the production of hysterical manifestations quite apart from debility or loss of weight. I am able to show you several illustrations of this.

CASE 3.—A young woman, aged 19 years, came to me in March, 1905, presenting a generalised rhythmical intention tremor, nystagmus, and all the symptoms of disseminated sclerosis. It is true that the disease had started suddenly five weeks before, after an hysterical attack of crying, but the symptoms appeared to me so characteristic that I could not help regarding the case as one of disseminated sclerosis. In extenuation of my error I may remind you of the impossibility in some cases of diagnosing hysterical tremor from disseminated sclerosis. I noticed, however, that her teeth were very defective and her gums ulcerated, and her mother stated that she had long been addicted to bolting her food and subject to constipation. I therefore prescribed for her salicylate of bismuth and cascara sagrada. After two months of this treatment she had made some improvement but the tremors and nystagmus still continued. In May she complained of swelling of the throat; the thyroid was noted as being large and the pulse was 140 per minute. The oral sepsis was remedied and the same treatment was persevered with, and by July all the symptoms had entirely disappeared. They have not returned since that time, now 16 months ago. Some might still regard this case as one of disseminated sclerosis with temporary improvement, but I would urge the sudden onset with a hysterical attack and the complete disappearance of all the symptoms of disseminated sclerosis. She still presents the hysterogenic ovarian reflex and complains from time to time of feelings of suffocation and I believe this case may be regarded as one of hysterical tremor determined by oral and gastro-intestinal sepsis.

CASE 4.—A married woman, aged 31 years, first came to the hospital in May, 1905, for hysterical attacks of various kinds. Sometimes these consisted of globus, sometimes of "dazed feelings," sometimes of trembling all over, with loss of power in the limbs. She has improved immensely under the same treatment as the last patient, and particularly during the last two months since she has taken castor oil regularly at night.

CASE 5.—A girl, aged 19 years, has been under treatment continuously since October, 1905, when she came for hysterical faints, attacks of suffocation, and inability to go on with her education as a pupil-teacher. I subsequently found she was passing mucus and "bits of skin in the stools" and after a prolonged course of treatment for mucous colitis she is now quite recovered from all the nervous and other symptoms.

CASE 6.—A girl, aged 16 years, came to the hospital in March, 1905, for convulsive seizures of considerable severity, coming on at each menstrual period ever since she first menstruated at the age of 14½ years, and occasionally in the intervals. As she was anæmic and constipated she was ordered iron and cascara with some improvement, though the fits still continued in a lesser degree. In November I discovered she had pyorrhœa alveolaris and a very notable enlargement of the thyroid, but without any of the other three signs of Graves's disease (proptosis, tachycardia, and tremor), which she told me had been noticed for a year or more, probably about the same time as the commencement of the fits. The defects in her teeth and gums were corrected in December, 1905; she has had no return of the fits for upwards of a year and feels quite well, though the thyroid is still slightly enlarged.

(*d*) I have during the last few years tried vaso-constrictors (e.g., ergot), vaso-dilators (e.g., pilocarpin), and remedies acting on the blood (e.g., calcium chloride) in cases of hysteria of various kinds, where there has been very noticeable irregularity in the vaso-motor regulator mechanism, or where I have had reason to suspect dilatation or constriction of the vessels of the central nervous system, usually in cases where other measures had failed. My efforts have not always been attended by success, for this is a new kind of treatment. Some of the cases I have recorded, and you may remember a young woman who was twice cured of her severe seizures by calcium chloride.[9] Another young woman who applied for flushings of the face and disagreeable obscure sensations all over the skin, sudden contractures of the field of vision, and dermatographia,[10] derived considerable benefit from the following prescription: extracti ergotæ, 3 grains; hamamelidin, $\frac{1}{2}$ grain; hyoscyamin, $\frac{1}{150}$ grain, thrice daily. Ergot seems to steady irregular vaso-motor action as well as to constrict the vessels, as the following case shows.

CASE 7.—A married woman, aged 32 years, came to the hospital in May, 1902, for attacks of "fear of impending death" followed by palpitation and staggering which came on usually in the street but also during the night without apparent cause. She also complained of nervousness, attacks of "shaking" and acroparæsthesia. She usually felt very cold but was also subject to "hot flushes." The hands were very blue. All these symptoms had come on gradually during the past few years. Since the age of 18 years she had been liable at times to go off into a trance lasting one or two hours, sometimes several times a day Her teeth were bad and I thought it wise first to have these attended to and the digestion improved by bismuth and diet. On Nov. 4th, 1902, I gave her calcium chloride (a remedy known to increase the coagulability of the blood), 20 grains thrice daily and nothing else but confection of senna once daily. The note two weeks later is that the "attacks of trance and other nerve symptoms are better; formerly one or two a day in series, lately none since taking med." But the digestion was upset and I had to return to the old medicine for a time. On Nov. 17th, 1903, I added extractum ergotæ liquidum (20 minims) to the medicine. This gave her very marked relief from the nervous symptoms. On Jan. 25th, 1904, it was noted that she was "so much better that she is taking the ergot medicine only once daily. The hands go white now instead of red." And for some time she ceased attending regularly. She still comes from time to time and whenever the ergot has been administered the nervous symptoms have ceased and they are now gradually disappearing. The case is interesting in this respect and also by the marked effect which the calcium chloride had upon the attacks of trance. Ichthyol, atropin, thyroid gland, and ovarian extract are also remedies which I have employed in various circumstances; but I hope to return to this subject on another occasion.

[10] The face of this patient is figured in the Clinical Journal, Jan. 9th, 1907, p. 197.

(e) Educational and other prophylactic measures are of great value when we remember the hereditary and inherent nature of this complaint. With careful education hysterical subjects may reveal brilliant intellects and a large proportion of them may become most useful and energetic members of the community. But when allowed to pass through a rigid form of schooling and to drag out a weary existence—circumstances commonly met with in the lower orders—they tend to gravitate into the workhouse, the brothel, or the prison. The cultivation of the will and of self-control is the central point in their education, so that the unruly reflex centres and emotions may meet their master in additional self-control. These children should be energetically, though with tact and kindness, taught to bridle their passions and to neglect small disagreeable sensations. It is of no use to get angry with them and call them shams; remember we are dealing with an individual of different nervous organisation and temperament from the average type.

The diet should be of the plainest and least stimulating kind, the life regular and free from any kind of excitement, and as much time as possible spent out of doors in contact with the grand but simple phenomena of nature. Nothing can be worse for these girls than the whirl and bustle of town life, nothing can be better than moderate exercise, bicycling, riding, or swimming. The question of sports where the exciting element of competition comes in must be carefully considered.

As age advances any tendency to introspection should, as far as possible, be quietly corrected, and especially by the cultivation of interests outside self. But, in guiding these people towards such counter attractions, screen them, as far as possible, from undue religious exercises and love affairs—two fatal directions which their fancies are very apt to take. On the other hand, the cultivation of the gentler qualities, pity, self-sacrifice, and work for others, leads to the formation of character and the self-control we desire. These people are often extremely selfish and if you can only cultivate unselfishness half the battle is won—self-control will surely follow.

If hysterical manifestations appear the patient should certainly be removed for a time from the family circle. I have sometimes found this alone sufficient to effect a cure. And even before any outbreak occurs it may be desirable, especially when the mother of the patient, as so often happens, is of an hysterical type, to consider the advisability of removing the girl or boy to the care of a judicious teacher or a suitable family. In these cases you will often be confronted with an unfortunate incompatibility between mother and daughter which will counteract all the good of the most careful education. Marriage, if suitable and happy, may prove to be the redemption of these subjects, not, as I have so often insisted on, by the gratification of the sexual passions, but by removal from incompatible surroundings, by giving to the patient fresh interests outside herself, and by the cultivation of unselfishness.

AND
T. P. LEGG, M.S. LOND., F.R C.S. ENG.,
ASSISTANT SURGEON TO THE ROYAL FREE HOSPITAL AND TO THE ITALIAN HOSPITAL, LONDON.

With an Account of the Blood Changes in the Second Case by
WALTER D'ESTE EMERY, M.D., B SC LOND., *Clinical Pathologist to King's College Hospital, London.*

CASE 1, *by* E W. ROUGHTON.—The patient, a child, aged seven years, was run over by a light van on Jan. 5th, 1906. On admission to hospital shortly after the accident she was found to be much collapsed, was pale and restless, the extremities were cold, and the pulse-rate was 120 per minute. Muddy marks on the clothing showed that a wheel had passed over the abdomen. I saw the child three hours after admission and found that the shock was still intense. The abdominal wall was hard and moving but little with respiration. Nothing else abnormal was detected. Feeling sure that there was some severe intra-abdominal injury, I decided to explore at once. On opening the abdomen a large quantity of dark-coloured blood escaped. The liver was intact but the spleen was found to be ruptured and in a pulpy condition. A ligature was passed round the gastro-splenic omentum and the remains of the spleen were removed. There were several loose bits. The peritoneum was sponged dry of blood and was filled with hot saline solution. The abdominal wound was closed as quickly as possible, only one layer of sutures being employed. During the operation saline solution was infused into the median basilic vein. The patient was much collapsed when she was put back to bed. Subcutaneous saline infusions were used during the next two days. For a week after the operation the temperature varied from 100° to 101° F. and the pulse from 120 to 140. Afterwards convalescence was only interrupted by a slight febrile attack on Feb. 10th and 11th, the cause of which was not ascertained. The patient was discharged on March 2nd.

The child was kept under observation until Dec. 4th, 1906. At no time was there any discoverable enlargement of lymphatic glands or alteration in the bones. The blood changes during the patient's stay in hospital are summarised in the subjoined table. The last column of the table gives a differential count of the white corpuscles nearly a year after the operation. The child was seen again in June, 1907: she then had some enlargement of the glands in the axillæ, groins, and on both sides of the neck. Her general health was quite good.

CASE 2, *by* T. P. LEGG.—On Nov. 25th, 1903, a little girl, aged 12 years, was admitted to the Royal Free Hospital. It appears that at 9 30 P M., whilst running in the street she fell against the kerbstone, striking the front of her abdomen. She went home and fainted. At 10 o'clock she was brought to the hospital. The child was in a good deal of pain; there was no evidence of any injury to the abdominal contents nor any bruising of the parietes. The pulse was 88 per minute. At midnight she was sleeping quietly, lying on her right side. The pulse had not increased in frequency; further examination did not reveal anything abnormal. During the night the pulse became more frequent hour by hour and next morning at 11 o'clock it was 128. The abdomen, which had become slightly distended, was distinctly rigid and tender on palpation, especially to the right of, and at the level of the umbilicus, where there was also slight discolouration of the skin. At this place there was an impairment of the percussion note; both flanks were resonant. The liver dulness was present. There had been no vomiting for several hours. The urine was normal. There was no marked facial pallor and the child was not restless. It seemed clear that some serious injury had resulted from the fall, the diagnosis lying between hæmorrhage and a rupture or severe bruise of the bowel. Exploratory laparotomy was performed, A SUMMARY OF THE BLOOD CHANGES IN CASE 1 DURING THE PATIENT'S STAY IN HOSPITAL, WITH A DIFFERENTIAL COUNT OF THE WHITE CORPUSCLES NEARLY A YEAR AFTER THE OPERATION.

an incision three inches long being made at the level of the umbilicus through the right rectus muscle, at the place where the rigidity was most marked and where the discolouration of the parietes existed. On opening the peritoneal cavity the omentum, infiltrated with blood, presented, and a large amount of dark blood with a few clots was evacuated. The incision was prolonged upwards to the right costal margin and the liver examined; it was found to be uninjured. The hand was at once passed across to the spleen which was felt to be extensively lacerated. A transverse incision across both recti muscles was then made, converting the former into a T-shaped incision. The spleen was readily brought up into the wound and the pedicle grasped by the fingers of the left hand. Around the hilum there was a large quantity of clot. The organ was freed from its peritoneal attachment, and a pedicle composed of the splenic vessels was formed and transfixed by three interlocking sutures, which were tied separately. Whilst the pedicle was being tied the respirations became hurried. The peritoneal cavity was washed out with sterilised salt solution, one and a half pints being left in it and one and a half pints being given intravenously during the operation. The wound was closed by interrupted silkworm-gut sutures passed through the whole thickness of the abdominal wall. The operation was well borne and six hours later the patient was quite comfortable. The pulse was 128 and irregular, three or four beats coming close together. A blood count was made; the red cells were 3,652,000, the whites 21,000, mostly polynuclear, and the hæmoglobin 63 per cent. The temperature was 100·8° F. On the 27th (the day after the operation) there was considerable abdominal distension but no rigidity. She had vomited frequently but only small amounts. The pulse at 6 P.M. was 154, of small volume and irregular, and the temperature was 101°. There was no restlessness. The bowels were well opened and on the 28th there was a marked improvement in the child's condition in every respect. From this time convalescence was uninterrupted and on Dec. 10th most of the stitches were removed, the wound having healed by primary union except at one place where the edges had not been sufficiently carefully approximated. She left the hospital quite well on Jan. 14th, 1904, having been kept in for purposes of observation. During the whole of this time repeated examinations of the lymphatic glands were made. On Nov. 27th a slightly enlarged gland above the left clavicle and on the 28th another in the axilla were found. They were never bigger than a pea. Later the glands in the right axilla and some in the posterior triangle of the right side were perceptible. These glands were never big and there was certainly none of the marked general enlargement of the lymphatic glands which has been noticed to follow the removal of the spleen in so many cases. There was never any tenderness in the long bones nor any enlargement of the thyroid.

A noticeable feature of the pulse was the manner in which two or three beats would come close together, and then for a time the beats would be quite regular. In the course of a few days this irregularity quite disappeared. The quantity of urine passed during the first 24 hours after the operation was 25 ounces, on the second day 25 ounces were passed, on the fourth day 46 ounces, and on the fifth day 36 ounces. During the next week the average daily amount exceeded 40 ounces. On two occasions the urea was estimated and was found to be 1·8 per cent. and 2·2 per cent. respectively. On Dec. 10th the patient had severe abdominal pain; this was probably due to intestinal disturbance secondary to a purgative. An enema resulted in a good motion and cessation of the pain. Severe griping abdominal pains have been noticed in several cases after removal of the spleen and are said to be due to the rapid enlargement of the mesenteric glands. With the exception of this attack the patient had not any abdominal pain and at no period could anything abnormal be felt in the abdomen. At the present time, more than three years after the accident, the patient is in perfect health.

Remarks by MR. LEGG.—Injuries of the spleen may be divided into two classes: (1) those without any external wound, and (2) those with an external wound accompanied by prolapse of the organ through it. The second group of cases will not be considered in the remarks which follow.

1. *The onset of the signs and symptoms.*—In the first case evidence of a serious intra-abdominal catastrophe was soon forthcoming. In the second more than 12 hours elapsed before there was evidence of anything seriously wrong. The hæmorrhage may have taken place slowly or have ceased for a time and then recurred, or the irritation of the peritoneum by the blood may have set up the severe symptoms. The fainting which the child suffered from soon after the accident was probably due to severe pain or shock. A similar delay[1] has been observed in many other cases. The actual amount of damage sustained by the organ has not a little to do with the rapidity of the onset of the signs. In our first case the spleen was pulped and in the second there were two fissures on the diaphragmatic aspect—one just below the middle line extending completely across the organ and the other a much shorter one nearer the upper pole at the anterior border. The splenic vessels[2] may be lacerated; when this occurs the hæmorrhage is likely to be very severe. Direct blows would appear to cause more frequently laceration, whilst a crush, as by a wagon, more often leads to pulping and disintegration.

2. *The nature of the injury.*—This varies from comparatively slight accidents, as a fall of a few feet, to a severe crush, such as being run over. Kicks and blows on the left side of the abdomen are not infrequent causes. There is frequently not any bruising or other signs of external violence, which emphasises the importance of putting all patients to bed after an abdominal injury has been sustained and carefully watching them, the pulse being taken regularly at not longer intervals than an hour.

3. *The site of the pain and the area of dulness.*—These are of so much importance in the diagnosis of abdominal injuries, and as the site of the operation is largely dependent on their position they are worthy of careful attention. In our first patient the child was in such profound shock as to be unable to feel pain and there was no area of dulness detected. In the second case the area of dulness, the most intense pain, and rigidity were to the right of the umbilicus. In many cases of ruptured spleen the greatest pain and tenderness have been found in the left hypochondriac and epigastric regions, with dulness in the same regions and in the left lumbar space. It is also to be remembered that there may be a very large amount of blood in the peritoneal cavity without any dulness being elicited on percussion, as in our first case.

4. *Methods of treatment.*—There are three methods of dealing with a ruptured spleen—(*a*) to suture the lacerations,

---

[2] Heaton: Brit. Med. Jour., vol. ii., 1899.

(*b*) to remove the organ, or (*c*) to pack with gauze. Each method has been successfully used. As regards the use of sutures they are not often applicable for the following reasons. 1. The size, number, and situation of the lacerations. It would seem to be scarcely possible to unite together sufficiently accurately two nearly separate portions. From their situation it may be impossible to reach all the lacerations and the time occupied in uniting the torn surfaces would be very considerable. Moreover, these patients are not in a condition to stand a prolonged operation. 2. The hæmorrhage may be temporarily arrested but when the shock passed off it would be not unlikely to recur, the stitches not holding in the friable spleen or cutting out owing to the variations in size of the organ which normally occur.

Removal of the injured spleen is the best method of treatment in the majority of cases and is the surest way of permanently arresting the hæmorrhage which can be temporarily controlled by grasping the pedicle with the fingers or by forceps. Two or three interlocking ligatures may be required. The pedicle should be divided as far from the ligatures as possible, a portion of the spleen being left behind if necessary. At the moment of tying the pedicle, there may be a change in the pulse and respiration. The hæmorrhage may have ceased at the time the operation is being performed, either because the patient is very collapsed or there is a good deal of clot about the hilum, or the pedicle itself is being stretched in bringing the organ into view.

There does not seem to be anything to recommend packing with gauze, especially as removal of the organ has been shown to be quite compatible with perfect health.

5. *Effects of removal of the healthy spleen.*—These can be studied from the numerous cases which are now on record.

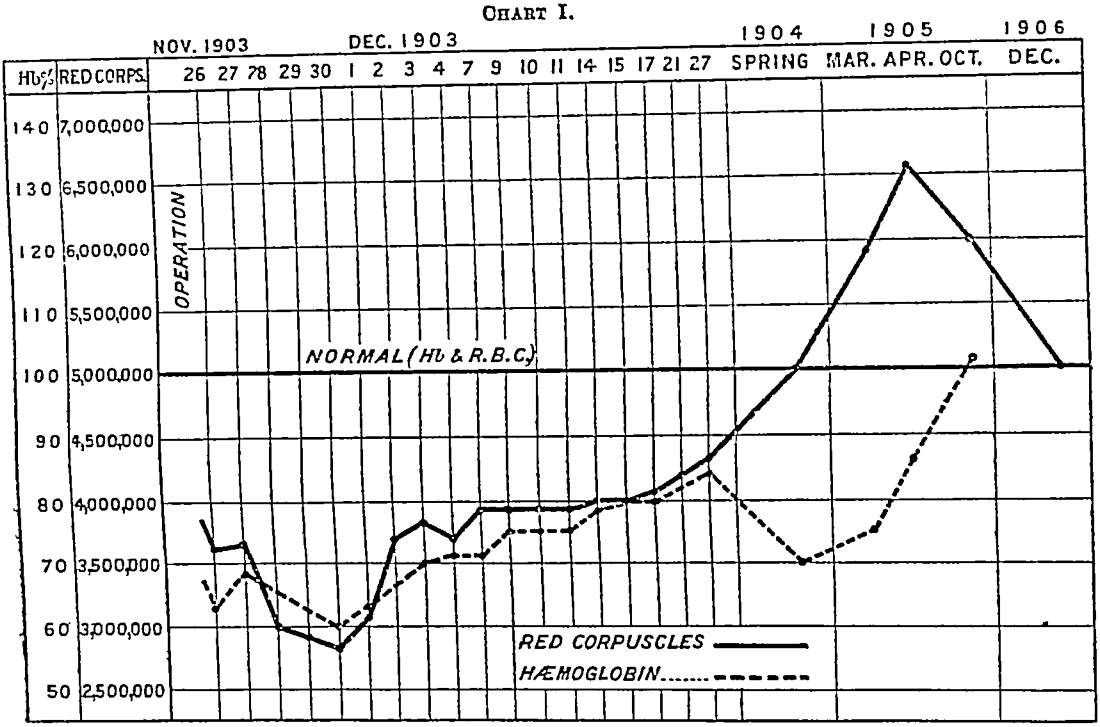
In many instances the patient has made an excellent immediate recovery from the operation and subsequently, after a varying interval of time, serious symptoms have developed. The patients may be divided into three classes: (1) those in whom convalescence and recovery is complete and rapid; (2) those in whom serious symptoms develop and persist for a time, being followed by a complete restoration to health; and (3) an intermediate group characterised by enlargement of the lymph glands, anæmia, some enlargement of the thyroid, and emaciation, a rapid recovery following. Age does not appear to have any determining influence as regards the onset of the symptoms. It would appear that in children recovery is generally rapid, as in these two patients.[3] In neither of them was an accessory spleen found, as has been sometimes observed. The symptoms which have followed the operation are: (1) rapid emaciation and weakness; (2) great thirst; (3) persistently rapid pulse; (4) intermittent elevation of temperature; (5) great anæmia; (6) drowsiness, peevishness, and irritability of temper; and (7) griping abdominal pain.[4]

CHART I.



Showing red corpuscles and hæmoglobin.

An Account of the Blood Changes in the Second Case,
by W. D'ESTE EMERY.

As it has been held that some theoretical questions of great importance might be solved by a careful examination of the blood after splenectomy, and as this did not seem to have been done in any reported case, we resolved to carry out a full series of researches in this case; it was extremely suitable for this purpose, since the patient was apparently quite healthy before the operation, the spleen removed at the operation was quite normal and the patient recovered without presenting any complications. In all 23 examinations of the blood have been made, 18 being within a month of the operation, one during the next year, three in the second, and one in the year after; the observations thus cover a period of three years, during the whole of which time the patient remained in perfect health and underwent the normal physiological growth of this period.

The counts were, with hardly an exception, made with the same apparatus and all were made by myself. The red corpuscles were counted with a Thoma-Zeiss hæmocytometer, special precautions being taken to ensure accuracy. For the hæmoglobin a Haldane's hæmoglobinometer was employed, the same apparatus being used throughout. The leucocytes were counted in the same preparation as the red corpuscles, using the field method and working with a field eight squares in diameter, as described in my "Clinical Bacteriology and Hæmatology."[5]

The differential counts were made in all cases on films stained by Jenner's stain and only perfect and well-stained films were used; in a few cases the results were checked with triacid stain. From 500 to 1000 leucocytes were counted and in some cases the counts were repeated and the results were compared. It was found that the correspondence was not always as close as could have been wished; this was due to the fact that the mononuclear cells (the lymphocytes and hyalines) showed an unusually great range of variability, so that the class to which a cell should belong was often uncertain. The results given in Table II. were obtained with considerable care and probably represent a close approximation to the truth. The results of the counts are given on Tables I., II., and III.

Red corpuscles and hæmoglobin (see Chart I.).—The first count was taken four hours after the operation and by this time the hæmorrhage had reduced the red corpuscles to 3,652,000 and the hæmoglobin to 63 per cent. The colour-index at this time was 0·86, but we are unable to suggest a reason why it should be below normal unless the patient was slightly chlorotic at the time of the accident. The second examination showed a rise, slight as regards the number of corpuscles but pronounced as regards the amount of hæmoglobin; this phenomenon is not uncommon after severe operations and is probably due partly to the restriction of fluids and partly to the defective circulation and consequent stagnation of blood in the capillaries. It has no relation to the absence of the spleen. The secondary fall beginning on the day after the operation and lasting until the fifth day (Nov. 30th) is also a normal phenomenon, and is due to the absorption of fluid to replace that lost by the hæmorrhage; the reduction is brought about simply by a dilution of the blood that remains. It will be seen that the lowest figures met with were 60 per cent. of hæmoglobin and

---

[5] Lewis's Practical Series, 1906.

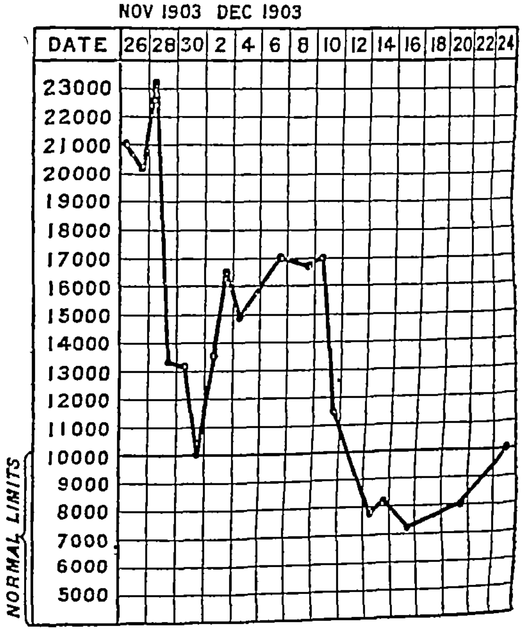
2,824,000 red corpuscles, indicating that some two-fifths of the total volume of the blood had been lost; this is a very considerable amount and one which may cause a severe strain on the organs of blood production, so that in a weakly person such a loss may be followed by anæmia of long duration. The process of regeneration appears to have commenced by the sixth day after the operation, which shows an increase of 3 per cent. of hæmoglobin and 300,000 red corpuscles over the preceding day. By the next day the increase was much more marked, the gain in red corpuscles during this period of 24 hours being 600,000, so that there was an increase of 900 000 during 48 hours. (It should be noted that the counts were made in nearly all cases at the same hour of the day.) From this point (the seventh day) there was a gradual and steady rise of both the corpuscles and the hæmoglobin, until the counts ceased on Dec. 24th, nearly a month after the operation. The red corpuscles were replaced slightly more rapidly than the hæmoglobin, so that the colour index was usually a little below normal; this is, of course, the normal process of regeneration. Lastly, a few normoblasts were found in the films during the second week—i.e., at the period of most rapid regeneration. It is interesting to note that a few myelocytes were seen at the same time, indicating great functional activity of the bone-marrow about this period. All these phenomena are quite normal and serve to indicate that the blood regeneration proceeds in an absolutely normal fashion after splenectomy. This appears to have been noted by the other surgeons who have performed the operation, to judge from the somewhat scanty data at our disposal. Thus in Pitts's and Ballance's[6] first case the regeneration was at the rate of 30,000 red corpuscles per day, in their second 20,000, and in their third 50,000. In another of Ballance's cases[7] the regeneration (taken from the date of operation to a month afterwards) was 45,000 per day, though, as in our case, the earlier stages were much more rapid. The loss of blood in these cases was not quite so great as in ours, the minimum being 3,333,333, 3,730,000, 3 590,000, and 3,280,000 respectively, whereas ours was 2,842,000. The hæmoglobin is not given in these cases except in Ballance's, but here it seems certain that some error must have crept in, since the figure never fell below 83 per cent. even when the red corpuscles were reduced to about 3,000,000. In Regnier's case, in which the hæmorrhage was very severe, the hæmoglobin fell to 20 per cent. and the red corpuscles to 2,500,000. The former reached 80 per cent. and the latter 4,700,000 in eight weeks —a formation of about 1 per cent. of hæmoglobin and 40,000 red corpuscles per diem.

The subsequent history of the case from the point of view of the red corpuscles is of some interest. An examination was made in the spring of the subsequent year (about four months after the operation) and there was found to be a slight grade of anæmia of the chlorotic type. The exact figures have unfortunately been mislaid, but the red corpuscles were approximately normal in numbers and the hæmoglobin reduced to about 70 per cent. A year after (in March, 1905, 16 months after the operation) the figures were: red corpuscles, 5,900,000 per cubic millimetre; hæmoglobin, 75 per cent., showing a decided increase in the number of red corpuscles, whereas the regeneration of the hæmoglobin had remained almost at a standstill, the amount being 10 per cent. less than a month after the operation. Considering that the onset of puberty probably took place at or about this time it is not at all improbable that this reduction (in which the colour index fell to 0·63) was of a genuine chlorotic nature.

In the following month (April, 1905, 17 months after the operation) the polycythæmia had increased to a remarkable extent, the red corpuscles numbering no fewer than 6,656 000 per cubic millimetre, the hæmoglobin being 86 per cent, and the colour index 0·64. The morphology of the corpuscles showed no deviation from the normal and there were no normoblasts or other abnormal corpuscles to be seen. We can suggest no explanation of these results, which do not appear to have been noticed previously in other cases. Six months subsequently to this the polycythæmia was still marked, though less than on the previous count. The red corpuscles were 6 000,000 and the hæmoglobin had by this time reached normal (102 per cent.), though the colour index was still low. It is obvious that these three counts happened luckily enough to have been taken at a time when some remarkable crisis occurred with regard to the formation of the red corpuscles and hæmoglobin, for in this period of seven months the hæmoglobin, which we may assume to have stood at about from 70 per cent. to 75 per cent. during the 16 months the patient had been out of the hospital, rose from 75 per cent. to 102 per cent., a gain of 27 per cent., whilst the corpuscles attained a maximum of 6,600,000 and then gradually sank. It is a little unfortunate that we have no counts immediately before and after this period. Our last count was made in December, 1906, almost exactly three years after the operation, and showed a perfectly normal condition of the blood so far as the red corpuscles and hæmoglobin were concerned: corpuscles, 5,000,000; hæmoglobin, 100 per cent. It is probable, therefore, that during the last 14 months the hæmoglobin had remained at its normal level, whilst the number of corpuscles had steadily sunk.

The leucocytes.—1. Total numbers (see Chart II.). The first count, immediately after the operation, showed a high leucocytosis which, as the differential count showed, was due entirely to an increase in the polynuclears. It remained nearly at the same level for two more days, the maximum of 23,000 being reached on the third day, about 50 hours after the operation. This leucocytosis was similar to that usually met with after severe injuries or extensive aseptic operations and does not present any point of interest. It rapidly diminished, and by the sixth day the numbers had regained a high normal level (10,000). At this period there was a secondary rise, lasting ten days (until Dec. 10th) followed by a rapid fall to normal (reached about the twelfth day) and attaining at its maximum a total height of 17,000 leucocytes per cubic millimetre. Subsequently to this the figures ranged between normal limits until the time when the examinations ceased on Dec. 24th, 1903 Our subsequent counts show that the total number of leucocytes was raised two years after the operation October, 1905), though on one occasion (April, 1905) a normal count was met with. The study of these total numbers is, however, of but little value in the absence of the differential counts.

CHART II.



Showing the total number of leucocytes.

2 Differential counts (see Table II., which deals with the percentage counts of the different varieties of leucocytes, and Table III and Chart III. which show their total numbers). The normal limits —The latter is the more instructive. The normal limits which are marked on the latter chart are, of course, only approximate, but may be taken as fair averages. The lymphocytes are considered as ranging between 1000 and 3500 per cubic millimetre, the polynuclears between 3000 and 7500. We will now consider each portion of the curve of the total leucocytes (Chart II.) in turn. (*a*) The initial rise, as has been noted above, is due entirely

---

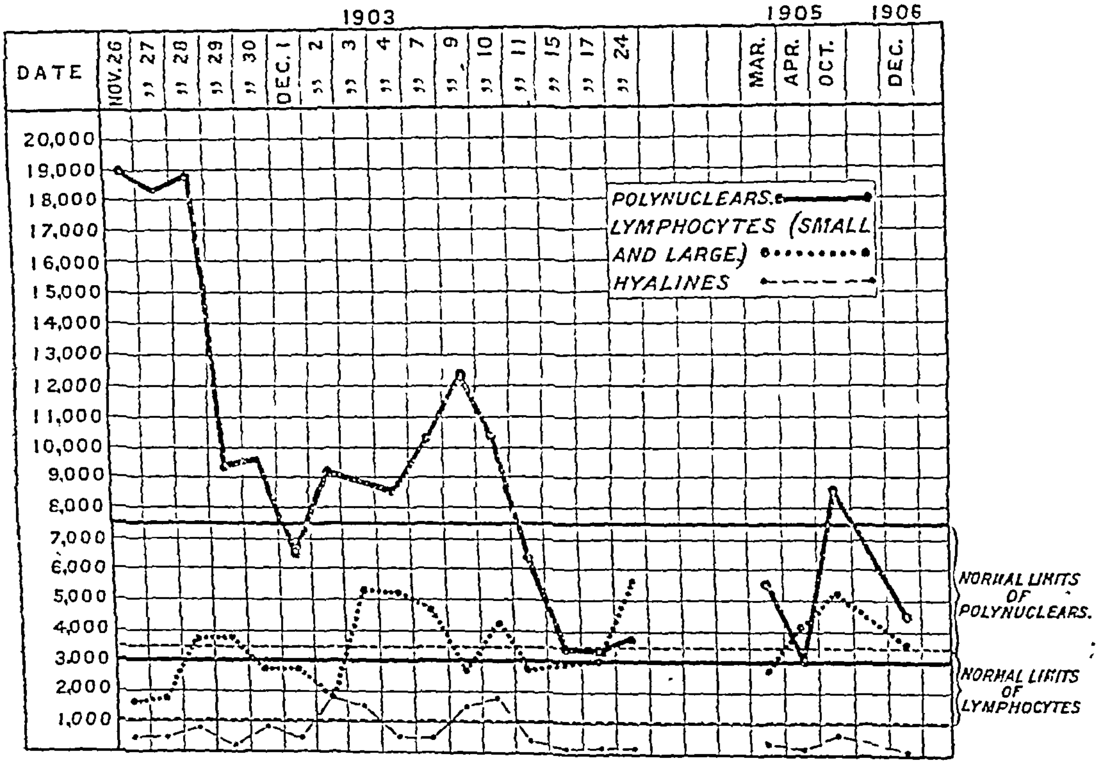
[6] Ballance and Pitts: Loc. cit.

[7] Loc. cit.

to a flood of polynuclears; the lymphocytes and hyaline corpuscles taken together formed as little as 8·75 per cent., but in spite of this the *total* lymphocytes did not fall below normal during this period. There were no eosinophiles at all to be found during this initial rise—a feature frequently met with in acute inflammations of whatever nature, and one which has no apparent connexion with the absence of the spleen. (*b*) The secondary rise, lasting from the fifth until about the tenth day, is of complex nature and is due mainly to an increase in the polynuclears, to a less extent to a lymphocytosis, and in some small degree to a reappearance of the eosinophile cells. In other words there was a mixed leucocytosis, such as is usually attributed to a stimulation of the functional activity of the whole of the blood-forming organs, especially perhaps of the bone marrow. There are several points to be noted which show beyond a doubt that there actually was a powerful stimulation of this tissue about this period. These are (1) the fact that this sudden rise of the leucocytes coincides almost exactly with the sharp rise in the red corpuscles and hæmoglobin; (2) that a few nucleated red corpuscles were present about this time; and (3) that myelocytes also occurred. But it would not be justifiable to assume that the whole of the changes are attributable to the bone marrow, for it was in the early portion of this period that the lymph glands were found to be enlarged and tender. The fall which terminated this second period of *leucocytosis was due almost* entirely to a diminution of the number of polynuclears. This is well shown on Chart III., where the fall is seen to commence on Dec. 9th and last until Dec. 15th, the range of numbers being between 12,474 and 3710—i.e., from a figure much above the normal upper limit to one just above the normal lower limit. We may fairly assume that the stimulation of the bone marrow ceased about Dec. 9th. During the subsequent period the lymphocytes were irregular, with perhaps a slightly downward tendency, but at the last examination of the first series (Dec. 24th) we find they had undergone a decided rise, reaching 5000 or 1500 above the normal level, at this date, the polynuclears remaining at a very low normal. It is unfortunate that the counts were not carried on for a few days longer, but the after history shows that in all probability there was actually a very decided total and relative lymphocytosis which commenced at this time and persisted for two years and perhaps for more. If we compare the total numbers of leucocytes on Dec. 1st and Dec. 24th we shall find the same (10,000) in each case, but these were very differently constituted:—

	Dec 1st.		Dec. 24th.
Total	*10,000*	......	*10,000*
Polynuclears, per cent. ...	65	......	38
" total	6,500	......	3,800
Lymphocytes, per cent. ...	28	......	58
" *total*	*2,800*	.....	*5,900*

CHART III.



Showing the total numbers of the various forms of leucocytes.

(*c*) In the counts made at an interval of more than a year after the operation we see figures quite comparable with those of Dec. 24th, with the exception that in two of the examinations there was a decided leucocytosis. In all but one of these there was a relative and absolute increase of the lymphocytes. The exception was in March, 1905, in which the lymphocytes reached 2900 (24·5 per cent.), and on this occasion there was an extraordinary number of hyaline cells (3000, or 25 per cent.) so that the exception is perhaps not a real one. At the last examination, more than three years after the operation, the blood, though normal in other respects, still shows a decided increase in the lymphocytes. These cells form 43·25 per cent. of a total count of 8800 per cubic millimetre. This is equivalent to 3800 per cubic millimetre, a figure slightly but decidedly in excess of the normal. The total number of the polynuclears is normal (4700), though their percentage is necessarily reduced (54 per cent.).

We may sum up these changes as follows. There was a marked polynuclear leucocytosis which fell to normal in about six days and then showed a recrudescence for some ten days, after which these leucocytes remained within normal limits. The lymphocytes, on the other hand, began to increase in numbers some seven days after the operation, and there has been a more or less marked lymphocytosis ever since.

The eosinophiles.—We have found no results which corroborate Ehrlich with regard to there being any eosinophilia after the operation. On the first three examinations these cells were absent. On the fourth day 0·5 per cent. were present, on the fifth 0·75, on the sixth 1·25, on the seventh 2·75, and on the eighth 4 per cent. After this the figures showed the variations usually met with in healthy persons. The normal totals are generally considered as ranging between 50 and 500 per cubic millimetre. In this patient the minimum (after the first three days) was 67 and the maximum 668; this was the only occasion on which the number 500 was exceeded, except in October, 1905, two years after the operation, when 555 were met with. We may fairly consider the counts as being quite normal in this respect and the absence of the eosinophiles during the first three days is, as has been pointed out above, not peculiar to cases of splenectomy.

The mononuclear cells.—We had hopes that a careful analysis of the mononuclear leucocytes, in the early period especially, might throw some light on the relations of these cells to one another and to this end we prepared a careful list of all the varieties of lymphocytes, hyaline cells, transitional cells, &c., met with. These were arranged under ten headings, the grouping being facilitated by careful micrometric measurements where necessary. The labour expended in the preparation of this table was very great and an inspection of our results led us to the opinion that no valid conclusion could be drawn from it, so that we have stated our results on ordinary lines and have not given this extended table. We found that there was no sort of sequence in the results which we obtained in this way, a form of leucocyte which occurred in large numbers in one day being entirely absent on the next.

An inspection of Tables II. and III. will show that the lowness of the total numbers of the lymphocytes which occurred immediately after the operation was due mainly to the scarceness of the small forms, of which there were less than 900 present, whereas the large lymphocytes and hyaline cells were in normal amount. For the next four days the small lymphocytes increased, reaching 3805, four times their initial number, whereas the large lymphocytes fell to 40 and the hyalines to 70. Then the reverse process occurred and the small lymphocytes showed a general downward tendency, though usually remaining within normal limits, whilst the larger forms, the large lymphocytes and the hyalines, showed a very decided rise. For example, on Dec. 3rd the small lymphocytes were 1200, a little above the normal minimum of 1000, whilst the large lymphocytes were 4100, about five times their normal maximum, and the hyalines 1700, their normal maximum being about 400. The predominance of large forms was a marked feature of this period, a period which, we may note, though without attempting to draw any inferences therefrom, roughly coincided with that showing signs of great stimulation of the bone marrow.

We noticed one cell which is rarely, if ever, seen in normal blood in films taken about this period. This was a very large cell, attaining nearly 20 μ, which in general appearance and staining reactions resembled large hyaline cells, but which had nuclei as contorted as those of polynuclear leucocytes. They occurred scantily and were counted as hyaline cells. They were entirely devoid of granules.

The last stage shows merely an increase of the small forms, the large lymphocytes and hyaline cells being normal (October, 1905, and December, 1906).

In our opinion it would be idle to attempt to draw any conclusions as to the site of origin of the mononuclear cells from these figures. We may, however, draw attention to the fact that in the first two counts after the injury the lymphocytes were decidedly low, though not below the lower normal limit (see Chart III.). At this period they commenced to rise and this rise was fairly parallel to the enlargement of the lymphatic glands, which was first noticed on Nov. 27th and had disappeared entirely by Dec. 7th. It is possible that this early rise is due to these glands taking on unusual activity and increasing their output of lymphocytes, the number of which is reduced owing to the absence of the spleen. It seems clear that this early rise (from 1570 on Nov. 27th to 3890 on Dec. 29th) is not due to any increased output from the bone marrow, since at this time the number of polynuclears was decreasing, suggesting that the stimulation of the tissue was diminishing. At the same time, we have seen reason to believe that what I have called the "secondary rise" in which the lymphocytes took part (from Dec. 1st to Dec. 11th, or thereabouts) was due to increased activity of the bone marrow. If any importance is to be attached to these observations they would go to prove the usually accepted view that the lymphocytes arise from all three structures—bone marrow, lymph glands, and spleen.

A CONSIDERATION OF SOME SYMPTOMS WHICH MAY BE PRODUCED BY SEVENTH CERVICAL RIBS.

By C. M. HINDS HOWELL, M.A., M.B. Oxon.,
M.R.C.P. Lond.,

CASUALTY PHYSICIAN TO ST. BARTHOLOMEW'S HOSPITAL AND REGISTRAR
TO THE NATIONAL HOSPITAL FOR THE PARALYSED
AND EPILEPTIC.

AN accessory rib, or pair of ribs, springing from the seventh cervical vertebra, are developmental anomalies with which all are familiar, but I venture to think that the characteristic symptoms to which they sometimes give rise are by no means so widely recognised. In these circumstances it seems worth while recording 16 cases which I have been able to collect and which illustrate the condition. Though cervical ribs produce definite vascular symptoms I wish chiefly to draw attention to the result of pressure, by these accessory ribs, on the brachial plexus. The class of cases to which I am about to refer has been described before on several occasions. Lewis Jones,[1] so long ago as 1893 in a paper published in the St. Bartholomew's Hospital Reports of that year, recorded several instances of symmetrical atrophies affecting the hands and occurring in young people. He gave a full clinical account of these cases, and they correspond closely with my series. At that time he ascribed them to the result of a neuritis, and did not suspect a seventh cervical rib as a possible exciting cause. It was Thorburn[2] who really first brought prominently forward the association of hand atrophy, resulting from pressure on the brachial plexus, with a seventh cervical rib in a communication to the Royal Medical and Chirurgical Society, published in the Transactions for 1905. In his paper he gives a description of four cases which had been under his observation and treatment, in two of which subjective sensory symptoms predominated; in the other two muscular wasting and sensory loss were the chief features. More recently still Lewis Jones,[3] writing in the September number, 1906, of *Medical Electrology and Radiology*, refers again to his cases. He has been able to trace 14 of his original series of cases and has demonstrated the presence of seventh cervical ribs in ten of these.

The frequency with which cervical ribs occur is difficult to estimate but they are by no means uncommon; four or five cases have occurred within recent years in the dissecting-rooms of St. Bartholomew's Hospital. In the majority of cases (about 70 per cent.) there are bilateral ribs, though they are not as a rule equally developed on the two sides. Llewellyn Phillips,[4] late demonstrator of anatomy at St. Bartholomew's Hospital, in the Proceedings of the Anatomical Society for 1900, described two cases which he had fully dissected. In the first case, that of a man, besides the cervical ribs there were various slight developmental anomalies present in the bony skeleton. The cervical ribs were bilateral but not symmetrical; that on the right side was fully developed, resembling closely the first dorsal rib, and consisted of head, neck, tubercle, and body; it articulated posteriorly with the sixth and seventh cervical vertebræ and intervertebral disc, and anteriorly with a cartilage which was ossified, and which in turn articulated with a cartilage joining the manubrium sterni. The rib on the left side was shorter and narrower and reached neither the sternum nor the first dorsal rib. The upper surface of each rib was grooved by the lowest trunk of the brachial plexus, which passed over it. Both ribs were moveable within narrow limits.

The second case was that of a woman, but the ribs, though similar, were not so fully developed, that on the left side being quite rudimentary. It was only about one inch in length, yet its upper surface was also grooved by a root of the plexus; it was firmly fixed, thus differing from the other three. The ribs received considerable muscular attachments from an extra intercostal muscle and from the scaleni. Perhaps the most important point in connexion with these cases is that they illustrate the relationship which may exist between the brachial plexus and even a rudimentary cervical rib. In these circumstances an imperfectly developed rib, which can hardly extend beyond the transverse process of the first dorsal vertebra, may yet cause pressure effects on the brachial plexus. The relation of the plexus to these ribs has been further disclosed by findings at operations for their removal. In one of my cases in which the rib was removed by Mr. W. D. Harmer, the rib, a large one, was found to push the lower part of the plexus forward in front of it, but, without an undue amount of dissection, it was not possible to determine accurately what root or cord of the plexus was most involved. In another instance, however, Mr. L. B. Rawling[5] at operation found the cervical rib lying between, and exerting pressure on, the eighth cervical and first dorsal root, which united a short distance beyond the rib. At first sight it appears difficult to see how a first dorsal root can come into intimate relation with a seventh cervical rib, but the direction of the first dorsal root on its way to enter into the formation of the plexus must be remembered. It passes almost directly upwards over the neck of the first dorsal rib and so might come without any difficulty into direct relationship with a seventh cervical rib which was growing somewhat downwards and forwards. That this is probable is shown by examining the appearances seen in skiagrams and comparing them with the clinical findings; as a rule, those ribs which appear to grow directly outwards from the spine do not cause pressure symptoms so often as those which seem to grow downwards and with a slightly forward tendency. Further, it is noteworthy that the longer ribs seem to produce symptoms less often than the shorter, stumpy ones. It is possible that the first dorsal root may be damaged by a seventh cervical rib without actually lying constantly in relation to that rib. The first dorsal root lies on the superior aspect of the neck and body of the first rib and may be compressed in this position between this rib and a seventh cervical one, more especially during lateral movements of the head and neck. The shortness of the ribs which produce symptoms, and the fact that improvement has followed removal of the first dorsal rib both point to this as a possible explanation in some cases.

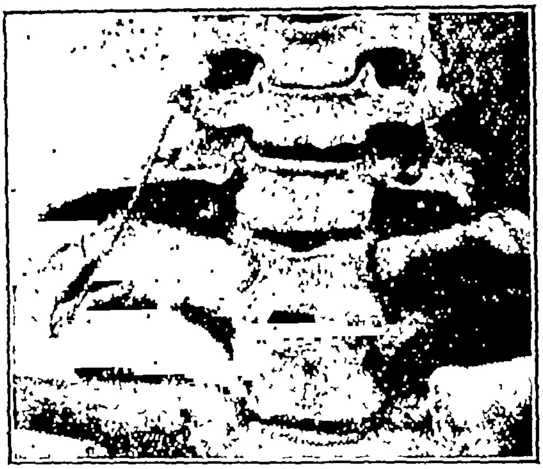
[4] Proceedings of the Anatomical Society of Great Britain and Ireland, 1900.

Gruber[6] classifies cervical ribs under four heads: (1) smallest type—rib does not project beyond transverse process, resembles articular end of a thoracic rib with head, neck, and tubercle, articulating with body and anterior aspect of transverse process of seventh cervical vertebra; (2) larger rib reaches a varying distance beyond transverse process, terminating in a free end or articulating with the osseous part of the first dorsal rib; (3) the rib may reach the first costal cartilage which it joins either by ligament or by direct contact; and (4) the rib is in all respects like a first dorsal rib articulating with the manubrium sterni.

I propose now to give a short description of my series of cases and subsequently to discuss certain points which arise in connexion with them.

CASE 1.—The patient, a female, aged 28 years, gave a history of pain affecting the radial border of the left wrist for the last two years. The hand was constantly cold and all symptoms were worse in cold weather. The left hand was weak and the patient constantly dropped anything she might be holding. She was in all respects normal except in the left forearm and hand. Flexion and extension of the wrist were weaker in the left than the right; flexion was most affected. The fingers were similarly weak. The grasp was weak, with some overaction of the extensors of the wrist and slight ulnar deviation. The muscles of the left hand were all much wasted, most markedly the thenar muscles and first and second interossei. As regards electrical reactions, in the extensors of the wrist and fingers there was some diminution to faradism; otherwise they were normal. The reaction of degeneration was present in the thenar, hypothenar, and first and second interossei, though there was no polar change; the third and fourth interossei appeared to be normal. Sensation: Subjective—as above. Objective—there was definite alteration in an area involving the ulnar border of the forearm corresponding to the first dorsal root distribution. Anæsthesia was moderate in degree with perhaps pain more affected than tactile sensation. The pupils were equal and the pulses at the wrist were equal. Nothing abnormal was felt in the neck. A skiagram showed well-marked bilateral seventh cervical ribs.

FIG. 1.



Reproduction of photograph of the cervical region of a female skeleton in the Royal College of Surgeons' Museum and reproduced by kind permission of the Council. The illustration shows bilateral but asymmetrical cervical ribs, that on the right side resembling a first thoracic rib in miniature, that on the left side being quite rudimentary and ankylosed. The photograph illustrates well how high the neck of the first rib is above the clavicle.

CASE 2.—The patient was a female, aged 21 years. There had been a history of pain for the last two years, which had been felt at first all over the right arm from the hand to the shoulder, and which later had settled along the ulnar border of the right forearm. A gradual onset of muscular weakness was noticed first when the patient attempted to cut wire with pliers. The muscles of the right hand were much wasted. This was most marked in the first dorsal interosseous and thenar eminence, the abductor, flexor brevis, and opponens pollicis suffering more than the adductors. The flexors of the wrist and fingers were affected in a slight degree. Electrical reactions in the forearm were normal. In the interossei there was marked diminution to faradic excitability; fairly brisk to galvanism (partial reaction of degeneration). In the thenar muscles there was well-marked reaction of degeneration; in the hypothenar partial reaction of degeneration. There was well-marked first dorsal anæsthesia. The pupils were equal, as were also the radial pulses. A skiagram showed bilateral cervical ribs.

CASE 3.—The patient was a male, aged 37 years, with a history of gradual and progressive weakness of the left forearm and hand extending over five years. There was an obvious swelling in the left supraclavicular fossa, with visible pulsation. The left forearm was markedly smaller than the right, with much flattening of the inner border, more marked atrophy of the hand muscles, and main-en-griffe. The grasp was very weak, with extension of the wrist, the flexors of the fingers and wrist having very little voluntary power. The aspect of the left arm resembled that seen in syringomyelia. The extensors of the wrist and fingers were affected also to a small extent. There was partial reaction of degeneration in the flexors (most) and the extensors of the wrist and fingers. No response was obtained in the hand muscles. There was no subjective painful sensation at all. There was marked sensory loss in the first dorsal and eighth cervical distribution. The pulses were unequal at the wrist, the right radial being almost double the left. The skin of the left hand and forearm was much cyanosed and the extremity was always very cold. A skiagram showed bilateral cervical ribs.

An operation was performed by Mr. Harmer on June 12th, 1906. A well-formed cervical rib was removed, about one and a quarter inches long, which did not articulate with the sternum or the first dorsal rib. It was seen that the lower cords of the brachial plexus were pushed forwards in front of the rib, and were under considerable pressure. The radial pulse improved immediately after operation. On June 27th the wound had healed by first intention and sensation was returning. On July 16th the anæsthesia was almost gone. It was noticed that the serratus magnus was very weak on the left side and showed partial reaction of degeneration. In December, 1906, the muscular power was much improved and the wasted muscles showed slight signs of filling out, the serratus magnus was greatly improved, while the electrical reactions were normal in the extensors, much improved in the flexors, but still absent in the hand. Sensation in the first dorsal area was normal. There was slight loss of sensation on the palmar and dorsal aspect of the terminal phalanges of the third and fourth fingers (remains of anæsthesia of the eighth cervical root).

---

[5] Medical Electrology and Radiology, September, 1906.

[6] Gruber quoted by Fürnrohr, Die Röntgenstrahlen in Dienst der Neurologie, 1906.

CASE 4.—The patient was a female, aged 42 years. The history of the case showed that the condition had commenced 20 years previously when very severe pains in the right elbow and the inner side of the right arm were experienced, so severe that she had to give up work, which always caused an exacerbation, as also did cold. Soon after the pain was first noticed the muscles of the hand began to waste. Flexion and extension of the wrist were weaker on the right than on the left. Flexor spasm was noticed in the second, third, and fourth fingers, and extension of the distal phalanges in these fingers could not be performed voluntarily. There was no power in the interossei, the thenar and hypothenar groups being much wasted and very weak. Electrical reactions appeared to be little affected in the extensors and flexors of the wrist and fingers. There was reaction of degeneration in the thenar and hypothenar muscles and there was no response at all in the interossei. There was anæsthesia in the first dorsal and eight cervical distribution. The right radial pulse was less than the left. A skiagram revealed bilateral cervical ribs. The patient has thought lately that the left hand is getting weak, but there is no evidence of this.

CASE 5.—The patient was a boy, aged 13 years. Six weeks previously, after swimming for too long a time, he had felt pain in the right wrist which was followed by weakness in that hand so that he dropped things. On examination no very marked wasting in the right forearm and hand was made out, but the hand was very slightly in main-en-griffe position, and there was marked weakness in the intrinsic hand muscles and very slight weakness in the flexors of the wrist and fingers. There was reaction of degeneration with polar change in the thenar group and in the first and second interossei, and reaction of degeneration with no polar change in the third and fourth interossei and hypothenar muscles. The forearm muscles were normal and the pulses were equal. There was slight diminution of sensation to light stimuli in the first dorsal area and there was more marked diminution to painful sensations. A skiagram showed bilateral cervical ribs.

CASE 6.—The patient, a woman, aged 43 years, had experienced the feeling of "pins and needles" in the right hand for 18 months. There had been pain for the last two months extending from the elbow to the little finger of the right arm of an aching character which was described as feeling "right in the bone." The pain was worse after exertion, and in cold weather, and at night. At the same time as the pain the patient first noticed that the right hand was weak, she could not wring clothes and when scrubbing could not get the floors clean, and she had difficulty in holding the needle when sewing, and in picking up pins, and so on. More recently she had had spasmodic contractions in the first and fourth fingers. The movements of the right arm all seemed slightly weaker than those of the left, though all could be well performed and with fair strength. Pronation and supination were slightly weaker in the right arm than in the left. Extension of the wrist was slightly weak; flexion was more affected and was definitely weak. There was less power in extending the fingers of the right hand than of the left and very much less power in flexing them. The thenar muscles were wasted, opposition and abduction being lost. In the interossei there was some wasting and they were definitely weak. The hypothenar muscles appeared to be practically unaffected. The grasp of the hand was poor. Sensation: subjective—as above; objective—slight tactile anæsthesia in the first dorsal distribution of the right side, analgesia was more marked, also slightly in the eighth cervical. There was typical reaction of regeneration with polar change in the thenar muscles and flexors of the fingers and partial reaction of degeneration in the interossei. The hypothenar muscles were normal. A cervical rib was palpable in the neck on the right side. The pulses and pupils were equal. A skiagram showed bilateral cervical ribs.

This case was operated on by Mr. Rawling at St. Bartholomew's Hospital on Jan. 24th, 1906. The abnormal rib was removed as far back as the transverse process of the seventh cervical vertebra. The rib was crossed and grooved by two nerve roots, though it was impossible to define exactly which they were. The wound healed by first intention. After the operation for two days the patient had lost power in the deltoid, triceps, and biceps, but this has steadily improved and their power is now almost normal. There has been no further pain in the arm and on testing, the sensory loss has almost entirely disappeared. The patient states that the wasted muscles have filled out a little and this seems to be the case. The operation is too recent for anything like considerable improvement to have occurred.[1]

CASE 7.—The patient was a woman, aged 33 years, and the symptoms had commenced when she was 28 years of age, at which time she first noticed numbness, followed by pain, along the ulnar border of the right forearm. This was followed by gradually increasing weakness of the right forearm and hand. The symptoms were unilateral. There was slight wasting of the flexor group of muscles on the inner side of the forearm—the flexors of the wrist seemed normal but those of the fingers were weaker in the right than in the left hand. The thenar muscles, especially the abductor and flexor brevis pollicis, were much wasted, as was also the first dorsal interosseous muscle—the remaining interossei and the hypothenar muscles showed only slight change. The second, third, and fourth fingers were held slightly flexed. There was reaction of degeneration in the abductor and flexor brevis pollicis, with partial reaction of degeneration in the interossei and hypothenar group. The reactions in the flexors of the wrist and forearm were normal. There was slight analgesia in the first dorsal root distribution, where, however, a light touch was easily appreciated. The pupils were normal and the pulses were equal. A skiagram showed bilateral but asymmetrical ribs.

CASE 8.—The patient, a girl, aged 18 years, had experienced the first symptoms—"rheumatic pains" in the left arm when wearing a tight coat—ten years previously. Four years before coming for treatment the arm had been twisted in play, since which time she had always felt pain in it, which was very severe sometimes, burning in character, and causing her to drop anything she was holding. The pain was situated chiefly in the middle of the biceps and in the middle of the forearm. A year later the hand began to get weak and to waste. The symptoms were entirely unilateral. There was a tender spot in the left supra-clavicular fossa and a hard lump could be felt, and when this was pressed upon pain was felt in the places referred to. There was no objective sensory change. The movements of the upper left arm were good and the power was the same as in the right arm. There was some flattening along the ulnar border. The hand was slightly in main-en-griffe position and the third finger was markedly over extended. Extension of the wrist and fingers was very slightly affected; flexion was markedly weak, the third finger being much weakest in flexion. The patient could not strike a note on a piano with this finger. There was wasting of the thenar eminence, with marked weakness in abduction and opposition of the thumb. Wasting was also marked in the interossei with guttering of the palm and dorsum of the hand. The hypothenar muscles also were *wasted but not to the same extent.* There was diminished response to the faradic current in the extensors of the wrist and fingers. The galvanic response remained brisk. Reaction of degeneration was present in the remainder of the muscles mentioned. Pulses: the left was much smaller than the right. A skiagram showed *double cervical ribs,* that on the *right side being much longer than,* and running in a different direction from, that on the left.

CASE 9.—The patient, a woman, aged 32 years, gave a history of pains on the *outer side* of the right arm extending over a period of 12 years. She thought the symptoms followed an attack of influenza. After this the hand began to waste. She had *suffered from cramp* in the fingers of the hand for several years when making any strain upon them and for the last few months had complained of involuntary twitchings of the third finger of the right hand. The forearm was not *wasted,* but the thenar group of muscles were much atrophied and movements were very weak. The interossei and hypothenar muscles seemed to have escaped. The electrical reactions were normal except in the thenar muscles, which did not respond at all. Sensation was normal and the pulses were equal at the wrist. A skiagram showed bilateral and very large cervical ribs, also considerable scoliosis in the cervical and upper dorsal region of the spinal column.

---

[1] The patient has now almost entirely recovered.

CASE 10.—The patient was a woman, aged 48 years, who gave a history of pains of long standing—she did not know exactly how long. She had had feelings of numbness and at times severe pain from the shoulder to the hand, both right and left, which were worse in winter and after exertion. The right thenar eminence alone was wasted and weak, all the other hand muscles seemed normal. There was reaction of degeneration in the wasted muscles, sensation was normal, and the pulses were equal at the wrist. A skiagram revealed bilateral cervical ribs.

CASE 11.—The patient, a woman, aged 54 years, gave a history of symptoms of long standing, the exact time being unknown. There had been tingling and numbness in the first and second fingers of the left hand, also slight flexor spasm in the third and fourth fingers, with abduction of the fourth finger. There was marked wasting of the interossei, but the thenar and hypothenar groups of muscles appeared to be normal. The muscular wasting was of recent origin, about one year. The was reaction of degeneration with polar change in the interossei and in the adductors of the thumb; all the other muscles reacted normally. There was slight diminution of sensation to light stimuli over the two outer fingers and thumb. The pulses were equal at the wrist. A skiagram showed bilateral cervical ribs.

CASE 12.—The patient was a girl, aged 11 years. The history of the case was that a year previously the patient had begun to complain of a dull aching pain, ill-defined in character and locality, in the left arm; shortly after this the thenar muscles of that hand began to waste and she had lost considerable power in the thumb. No other muscles were affected, but the thenar group showed marked wasting. There was reaction of degeneration in the affected muscles. Sensation was not abnormal and the pulses were equal. A skiagram showed bilateral cervical ribs, that on the left side being most prominent and the right rib being very rudimentary.

CASE 13.—The patient, a woman, aged 49 years, had had tingling sensations along the median nerve distribution in the right hand for two years. Loss of power in the thumb followed, associated with wasting of the abductor and flexor brevis pollicis and spasm in the adductors of the thumb. There was reaction of degeneration in the wasted muscles. The sensory changes were very slight diminution to tactile and painful stimuli in the distal phalanges of the thumb and the first and second fingers on the palmar and dorsal aspect. The pulses were equal at the wrist. A skiagram showed short bilateral cervical ribs.

On July 12th Mr. Sargent operated and removed the right cervical rib. It did not seem to be exerting any particular pressure on the cords of the plexus. No injury was done to the plexus at the time of the operation. On the 21st all movements in the arm were lost except slight flexion of the fingers. At the present time (January, 1907) the patient writes to say that the arm is still much weaker than before operation. She can almost get her arm straight above her head but she cannot get her hand behind her back. She can almost put her hand on the top and back of her head but she has very little power in it. The thumb has not got any stronger, but the wasting away seems to have stopped and the muscles have filled out, but only slightly.

CASE 14.—The patient, a woman, aged 29 years, gave a history of pain in the right thumb and radial border of the arm 18 months previously. The onset had been sudden. The pain was always made worse by exertion. Muscular wasting in the thenar group followed the pain, but no other hand muscles were affected. There was reaction of degeneration in the wasted muscles. The sensory changes were similar to those described in Case 13. A skiagram showed bilateral cervical ribs. The wasted muscles improved slightly after an operation in which the first dorsal rib was removed.

CASE 15.—The patient was a woman, aged 40 years, with a history of symptoms of six months' duration. There had been pain in the left shoulder and down the left arm, with "pins and needles" at times. It was worse when the arm hung down by the side or after exertion, especially after washing. A tender spot was felt in the supraclavicular region on the left side. The hands were said to feel weak, but no muscular wasting was noted and the electrical reactions were normal. There were no sensory changes. A skiagram showed short bilateral cervical ribs.

CASE 16.—The patient, a female, aged 27 years, gave a history of pain on the dorsal aspect of the right hand and a "tired feeling" along the inner side of the right forearm which had lasted for ten months. There was no muscular wasting, the electrical reactions were normal, and there were no sensory changes. A skiagram revealed bilateral cervical ribs.

In none of the above cases was any further change discovered in the nervous system than that described in the text. In no case were any sympathetic symptoms noted.

It will be seen from the above series that individual cases might be selected which differ widely from each other, and this fact might be used as an argument against the cervical rib as the common causative factor in all. I must admit that to some extent this is true, but it is only in the last two cases, where subjective sensations alone existed, that the diagnosis is really in doubt; and Thorburn, in his paper already referred to, has described cases very similar where operative procedure and removal of the cervical rib conclusively established the diagnosis by removing the pain. In the remaining cases the difference is only one of degree; I regard the first eight cases as typical examples of the fully developed symptom complex caused by pressure on the brachial plexus by the seventh cervical rib.

Before proceeding to analyse these cases it is necessary to establish the accuracy of the diagnosis. The only possible conditions which could produce similar symptoms, or symptoms at all comparable to those quoted, would be syringomyelia, anterior poliomyelitis acuta or chronica, peripheral neuritis, and the class of cases described by Farquhar Buzzard[8] as uniradicular palsies of the brachial plexus.

From syringomyelia the diagnosis is almost self evident. Ocular changes, common in this condition, are almost unknown in connexion with cervical ribs, nor are the reflexes in the latter condition abnormal. Sensory changes in the cervical rib cases are confined to the first dorsal or eighth cervical root distribution, though within these areas dissociative changes are to a certain extent met with. Scoliosis in the cervical region is occasionally met with but not to any great extent. Any sensory changes when present at once exclude either an infantile paralysis or progressive muscular atrophy. Further, the onset in infantile paralysis is usually distinctive, and, moreover, it is rare to find the hand muscles alone affected in this disease. From progressive muscular atrophy the diagnosis in the absence of sensory changes may be more difficult but the progress of the two cases is quite dissimilar. In progressive muscular atrophy both hands are affected sooner or later, whilst many of the rib cases remain strictly unilateral; nor are the reflexes ever increased in the latter condition. Further, the electrical reactions differ; whereas in progressive muscular atrophy the rule is for a simple diminution to the faradic and galvanic currents to exist, in the cervical rib cases one meets with reaction of degeneration in its most typical form. This only occurs in the former case when the disease is running a very rapid course, in which case the diagnosis could not long remain in doubt.

From peripheral neuritis, the root distribution of the muscular wasting and the sensory loss (when such is present) make diagnosis easy. With regard to Buzzard's cases of uniradicular palsies of the lower roots of the brachial plexus the diagnosis without an x ray examination is well-nigh impossible. The clinical picture in both cases closely corresponds, for both are due to a lesion which chiefly affects the first dorsal root. Of the two conditions I think that caused by a cervical rib is by far the commoner, for of the eight cases in which the muscular wasting and sensory loss corresponded to some of the cases described by Buzzard the skiagram showed the presence in all of definite cervical ribs. In two of these cases the ribs have been removed, with marked improvement resulting. This result of operative interference is, of course, the strongest link in the chain of evidence pointing to cervical ribs as the cause of the symptoms described. All operations have not been equally successful, it is true, but I think sufficient have been so to prove the point conclusively. Besides the two cases of my series which have been operated on with marked benefit and a third (Case 14) where improvement has been slight, the *following successful cases have been recorded:* Thorburn[9] two, Weber[10] two, and Seiffer[11] and Déjerine[12] one each.

---

[8] Brain, 1902.

I think it is fair to conclude from the above evidence that a seventh cervical rib does give rise at times to certain well-defined *symptoms from pressure on the roots* of the brachial plexus, that in fully developed cases the diagnosis is easy and that a skiagram should, of course, be taken to confirm the diagnosis; lastly, that a number of cases also occur in which *minor degrees of muscular wasting and sensory changes* exist. Analysis of the cases collected brings out several interesting points.

Sex.—14 out of the 16 cases were in women and the reason for *this is by no means obvious;* there is nothing to show that a cervical rib is commoner in woman than in man, nor can laborious occupation be an exciting factor, or we should have expected to find the preponderance of cases in men. Possibly *certain arm movements* may bring the plexus more into direct relation with the rib, as, for instance, scrubbing floors, but the women in whom the condition has occurred are not all charwomen. Possibly the more thoracic type of respiration in women may exert some influence, but such influence must be slight indeed.

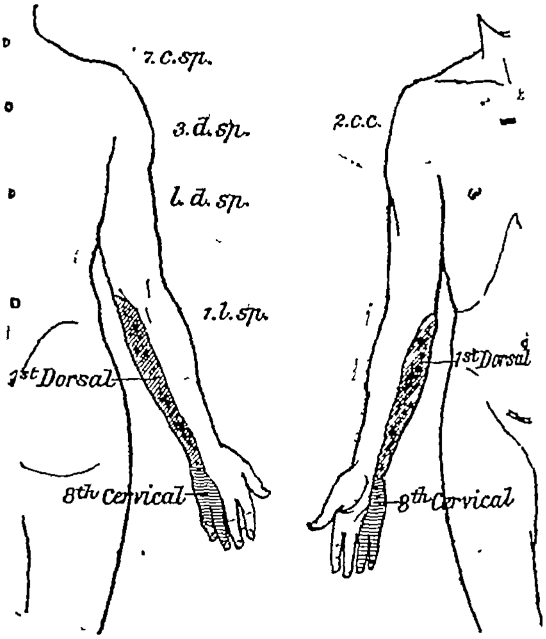
Age.—10 out of the 16 cases occurred in persons under the age of 30 years, the explanation of this no doubt being that *this period corresponds to the more active growth* and ossification of the ribs. In the cases occurring at a later age it is possible that the increasing rigidity of the accessory rib, perhaps going on to firm ankylosis, may be responsible for the production of symptoms, which the rib in a more moveable condition had failed to produce.

Sensory changes.—Both subjective and objective sensory disturbances are met with, the former being almost invariably present, while the latter were noted in nine of the cases. Pain is the predominant feature of the subjective changes and is specially influenced by exertion, in which the arms are involved, and by cold. *The patients always complain* more in winter than in summer. The pain may be severe—in one case it was so pronounced that the patient had to give up work; it is variously described as "sharp rheumatic pain," a "dull aching in the bone," "burning pain," and so on. Numbness and tingling were pronounced in two cases. The situation to which the pain is referred has varied, but is usually stated to extend from the shoulder to the hand on the affected side, being specially noticeable at the elbow and along the ulnar side of the forearm.

Objective changes.—The typical thing is undoubtedly loss in the distribution of the eighth cervical and first dorsal root *(vide diagram), the latter being the most affected, and sometimes* existing alone; I have never found a case where the eighth cervical loss was present alone; as a rule one finds slight dissociation phenomena, the tactile loss being less pronounced than the analgesia. This was also a feature of Buzzard's cases and indicates a root lesion, as Sherrington first pointed out. Déjerine[13] has recorded a case in which a cervical rib was accompanied by paræsthesia and definite sensory loss in the fifth and sixth cervical distribution. The rib was removed and the sensory disturbances cleared up subsequently to the operation. In three cases there was very slight tactile diminution found over the thumb and first and second fingers, the change being most marked, but never profound, over the dorsal and palmar aspect of the distal phalanges. In two cases the changes were purely subjective and unaccompanied by any muscular weakness or wasting, and the electrical reactions of the hand muscles were normal.

Motor system.—Muscular wasting and weakness are in most of the cases chiefly noticeable in the intrinsic hand muscles, but in the more severe cases the flexors of the wrist and fingers may be considerably affected—the fingers, as a rule, more severely than the wrist muscles. The grasp is weak with extension of the wrist and the hand at rest in the pronounced cases assumes the main-en-griffe position. Wasting and muscular disability are usually most marked in the thenar muscles, and of these the abductor and flexor brevis seem to suffer most; in some cases these are the only muscles affected to any considerable extent. The interossei and hypothenar muscles suffer to a less extent. There may be some degree of spasm in the flexors of the third and fourth fingers in cases where the muscular paralysis is not far advanced. Thorburn noted this point in his cases. There is sometimes abduction of the little finger. Even in cases of long standing the electrical testing of the affected muscles showed the presence of reaction of degeneration in its typical form, though where the muscular wasting was excessive the electrical response to galvanism, as well as faradism, could not be obtained. In all the recent cases reaction of degeneration was present. The motor and sensory changes thus point to a lesion which, in the majority of cases, involves chiefly the first dorsal root, with less interference with the eighth cervical root, which indeed may entirely escape.

FIG. 2.



The shaded areas represent the distribution of the sensory loss met with in complete cases of cervical ribs. Analgesia is as a rule more pronounced than tactile anæsthesia in these areas.

Other phenomena which have been attributed to cervical ribs.—Sympathetic nerve: In none of the cases here recorded was there any affection whatever of the cervical sympathetic, but Fürnrohr[14] records an instance of sympathetic *eye symptoms* associated with a cervical rib. The patient, a young girl, had complained for about six months of widening of the palpebral fissure and proptosis of the right eye; the right pupil was noticed to be wider than the left, the thyroid gland was slightly enlarged, and the right carotid pulsated more violently than the left. A radiogram showed a rib growing from the sixth cervical vertebra. *It is not stated whether the rib was removed, with the subsequent* cure of the symptoms.

Scoliosis.—According to Fürnrohr,[15] Garré[16] first drew attention to this symptom as a possible complication of cervical ribs. There is, he says, a displacement of the scapula on the same side as the cervical rib upwards and outwards and a deviation of the vertebral column, with the convex curve *towards* the accessory rib, in the cervical region, whilst a compensatory curve in the opposite direction is met with in the lower dorsal vertebræ. This scoliosis *is by no* means a constant feature and by many is regarded as accidental so far as the rib is concerned. Though only markedly present in one of my cases (Case 9) it occurred to a less extent in two others (Cases 1 and 4).

Syringomyelia.—This has been described by Oppenheim and others as occurring in cases where the radiogram has shown the presence of cervical ribs (the ribs being regarded as part of a widespread developmental anomaly). I do not know if any evidence exists to show that cervical ribs are more common in patients with syringomyelia than in others.

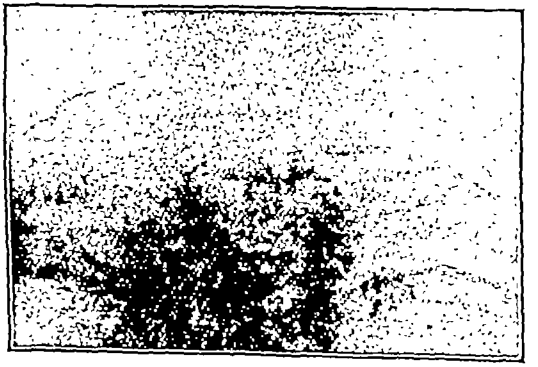
It is quite possible that the simultaneous occurrence of the two conditions may have been simply accidental.

A word as to radiograms and their interpretation in cases where a rib is suspected. The photograph is best taken with the patient in the dorsal decubitus and the plate behind the neck. With a "low" osmium tube of about 5-inch spark gap and a 10-inch coil I think an exposure of from one and a half to two minutes has given the best results. It is sometimes difficult to say whether a definite cervical rib or a rather abnormally developed tranverse process of the seventh cervical vertebra is present. I have photographed a skeleton where these transverse processes are particularly well developed, but in the radiogram they do not nearly reach in lateral extent the extremity of the transverse process of the first dorsal vertebra. I think that a transverse process or rudimentary rib, which extends beyond the first dorsal transverse process, should be regarded as a potential factor for the production of pressure symptoms. Phillips's dissection, already quoted, supports this view.

As a result of a number of radiograms of the neck taken at the National Hospital one has noted that in the first place cervical ribs may be present and produce no symptoms, and secondly, that though nearly all the cases of cervical ribs are bilateral—in the greater number the symptoms are unilateral. The explanation of this, I feel sure, entirely depends on the direction of growth taken by the rib. Those ribs which grow straight out from the spinal column or incline a little backwards (and therefore show most conspicuously in radiograms) are little liable to produce pressure symptoms. Whilst the rib which seems to grow forwards, or forwards and downwards, is almost invariably associated with some injury of the plexus.

The treatment of the various conditions produced by cervical ribs may be divided broadly into (1) palliative and (2) radical.

FIG. 3.



Bilateral and symmetrical cervical ribs (Case 4).

Palliative treatment.—This consists in rest to the arm as much as possible, the use of blisters as counter-irritants if subjective sensory phenomena are conspicuous, or the use of the constant current over the painful areas. The anode should be used as the active electrode and a current of 8 to 10 milliampères employed. In some cases this will suffice to remove the greater part of the pain, aided perhaps by the use of a liniment composed of mesotan and olive oil, in equal proportions, care being necessary to prevent irritation of the skin by this method. For the muscular condition much can be done in the slight cases by massage and the use of electricity, using a combined faradic and galvanic current sufficiently strong to produce a medium contraction in the affected muscles. Under this treatment some of the cases will show a decided improvement, but more probably will not. In some cases the painful sensations cease of themselves and the muscular wasting becomes arrested, leaving a hand that is still useful though not normal, the thumb movements being most restricted.

Radical treatment.—The question of operative interference is raised when the pain is extremely severe or when muscular wasting has advanced to such an extent as to interfere considerably with the utility of the hand, but in my opinion palliative treatment should always first be given a trial. In the slighter cases I do not think that operative interference is to be recommended as it is not attended by universally satisfactory results. When undertaken it is most important that it should be complete, by which I mean that the periosteum should be removed with the rib. The necessity for this is shown by a case which Weber has recorded, where a subperiosteal excision was first performed with temporary relief of pain, but new bone was formed and the symptoms recurred to be ultimately cured by a complete removal. Unsatisfactory results sometimes occur. I have seen two cases, and another is recorded by Fürnrohr,[17] where a more or less complete paralysis of the whole arm (especially affecting the deltoid) occurred after the operation, and this, too, without any obvious injury being done to the plexus at the time. One of these cases proved most intractable, but the other two cleared up almost completely within two months. The brachial plexus seems to resent any such handling or stretching, as is almost unavoidable during the operation. In another case a paralysis with reaction of degeneration resulted in the serratus magnus and though this ultimately improved very much the muscle has not yet, seven months after the operation, completely recovered. When one remembers the course of the posterior thoracic nerve it is not difficult to realise how easily it might be injured in the manipulations necessary for the removal of a seventh cervical rib. An important point for the surgeon to bear in mind is that the cervical rib lies much higher in the neck than is usually expected. The first dorsal rib has in several instances been mistaken for a seventh cervical rib and at times has been removed in error—a mistake which may be easily made when one recollects that the latter may articulate with the sternum, has muscular attachments from the scalene and intercostal muscles, and in some cases is crossed by an abnormally high subclavian artery.

Mr. Rawling, who very kindly operated on one of my cases, has expressed himself to me on the subject as follows. He bases his remarks on two cases on which he has operated himself and on two others which were operated on at St. Bartholomew's Hospital. 1. The ribs in all these cases have been short, projecting only from 1 to 2 inches beyond the tip of the transverse process. The ribs were directed outwards for a short distance and there turned markedly downwards and forwards. 2. The upper aspect of the rib is definitely grooved by a nerve trunk, though it is not always possible without testing electrically to identify which trunk is present. 3. Complete removal is usually a matter of very great difficulty, due to the small area of operative field and the numerous muscular attachments which the rib receives. In removing these many small, but troublesome, vessels are divided. 4. The rib is by no means easy to find. It seems to lie in such a manner that its tip is embedded in the substance of the scalenus medius and posticus muscles. It also lies at a very much higher plane than is usually anticipated, the very great obliquity of the first rib being forgotten.

In conclusion I wish to express my best thanks to those members of the staff of the National Hospital who have most kindly allowed me to make use of their cases.

Queen Anne-street, W.

A CASE OF ACUTE LEUKÆMIA (LYMPHOCYTHÆMIA).

BY HAROLD H. E. SCATLIFF, M.A. OXON., M.R.C.S. ENG.,
ASSISTANT SURGEON TO THE BRIGHTON THROAT AND EAR HOSPITAL;
AND
EDMUND HOBHOUSE, M.D. OXON.,
PHYSICIAN TO THE SUSSEX COUNTY HOSPITAL.
With Pathological Notes by F. G. BUSHNELL, M.D. Lond.,
Pathologist to the Sussex County Hospital.

THE patient, a man, aged 20½ years, an Englishman, though resident in Morocco for a good part of his life, was first seen on Jan. 2nd of this year. He complained of a swelling on his leg of three days' duration. There was a large hæmatoma of the size of an egg, fluctuating in the centre, and situated over the internal saphenous vein of the right leg; the inguinal glands were enlarged and tender, and the temperature was 101° F.; there was no thrombosis in the vein above or below. There was no history of local trauma, the lump having appeared spontaneously, but three weeks or a month before this the patient had burnt the dorsum of the foot on that side and thought he had poisoned the wound with a coloured sock, as the burn did not completely heal till about a week before he was seen on Jan. 2nd. The swelling was opened by Mr. A. H. Buck under a general anæsthetic and sanious pus was evacuated; at the same time it was noted that there were several small subcutaneous hæmorrhages or bruises on the toes. The temperature went down for a day or two and the swelling of the inguinal glands disappeared, but the wound, though clean, showed no tendency to heal as it should. The patient at the time felt very well. On Jan. 12th his temperature rose to 101° again and there was offensive and frequent diarrhœa. A dose of oleum ricini was given and subsequent treatment with no improvement. As the symptoms on the 12th resembled those of septic poisoning Dr. Hobhouse was asked to see the patient. Meanwhile the sputum had been tested and a Widal examination had been made, but both with a negative result. Dr. Hobhouse suggested a blood examination for septic organisms. The patient was taking medicinally at the time salicylate of bismuth and quinine, and as regards his general condition he had a daily septic temperature, no headache, slight enlargement of the spleen, hæmic murmurs over the base of the heart, and spongy gums. The diarrhœa stopped on the 16th, but the cervical glands were enlarged and tender on both sides.

---

[17] Die Röntgenstrahlen in Deinst der Neurologie.

Dr. Bushnell sent the following report from his blood examination: "Mr. H. Scatliff asked me to undertake a bacteriological examination of the blood. Ten cubic centimetres were sown in 250 cubic centimetres of bouillon on serum and agar. In 24 hours, at 37° C., a distinct turbidity was noticed in the broth and was found to be due to bodies resembling micrococci in appearance, size, and staining reactions. At the time these were thought to be staphylococci, but in the absence of growth in subculture on this and on several subsequent occasions in bouillon and blood cultures they may be regarded as artefacts from the presence of particles of (?) proteid nature (doubtless such forms would be instanced as evidences of spontaneous evolution of life by some observers). Blood-films showed a marked lymphocytosis."

As the blood from the last note of Dr. Bushnell appeared to be that of a patient suffering from leukæmia as well, he made a further blood count, quantitative and qualitative, as follows:—

"Blood examination showed—hæmoglobin, 40 per cent.; red cells, 2,240,000 per cubic millimetre; and leucocytes, 64,300 per cubic millimetre.

Differential Count of Leucocytes.

—	Per cent.	Absolute number.	
		Patient.	Normal.
Polymorphonuclear...	18·5	11,895	6500
Eosinophiles	2·3	1,478	300
Small lymphocytes	20·8	13,374	2500
Large „	50·8	32,664	
Transitional cells	6·0	3,858	—
Myelocytes	0·5	321	—
Hyaline cells	0·5	321	600
Mast „	—	—	100

Remarks.—There is severe anæmia with colour index approaching normal (0·9) and a tenfold leucocytosis with 18 times the number of lymphocytes normally present and twice the number of polynuclears. The polynuclears are practically non-granular with Leishman's stain and a large number of the lymphocytes have a few neutrophilic granules and are vacuolated. The blood is characterised by the absence of the differentiations present in the leucocytes of the elaborated normal blood. In the apparently purposeless proliferation of these cells and in the fatal cachexia ensuing we have evidence of a malignant new growth of the blood cells of the nature of a sarcomatosis. The cachexia would appear to be due to misappropriation of nourishment by these leucocytes. As has been pointed out before by me,[1] and as is exemplified here, we have connecting links between simple growths and malignant neoplasms and between leukæmic, lymphadenomatous, and sarcomatous affections (i.e., blood diseases and malignant growths). The greatest interest lies in treatment and in the importance of elucidating the nature of recoveries in man and lower animals (mice) from spontaneous or experimentally produced malignant neoplasms."

It was now apparent that the original hæmatoma was only a symptom of the disease, that is a manifestation of the multiple hæmorrhages which followed so rapidly. The patient at this time was very cheerful, with a daily temperature of 101° F. in the morning and between 99° and 100° in the evening (see chart). Eight weeks before this date he had played hockey for his college, feeling, however, greatly done up after each game. The subsequent history is shortly as follows.

On Jan. 27th epistaxis started but was easily controlled. The cervical glands alone were enlarged. There was a continuous evening temperature. The leg wound started healing. There was no albumin in the urine. The patient was in the fresh air as much as possible, being fed up and taking iron and arsenic, the latter in increasing doses, and pills of calcium chloride.

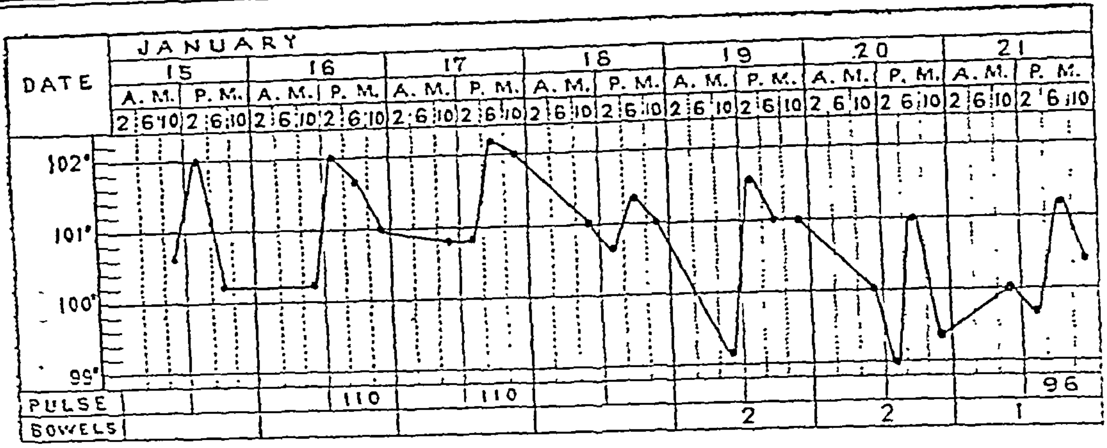
On Feb. 3rd there was epistaxis as a rule every other day, not from any bleeding spot, but capillary oozing from the mucous membrane, both on the septum and turbinals; it was easily controlled by a strip of gauze in the anterior nares for half an hour. The cervical glands were less enlarged and the temperature was rather lower each day, but always above 99°. The gums were very spongy and bled readily. The spleen was two and a half fingers' breadth beyond the costal margin. About this time a short trial of the x rays was made but was discontinued. Towards the end of February the epistaxis was more frequent; there was a large submucous hæmorrhage on the soft palate. The mucous membranes were now very anæmic and the skin was sallow. There was dyspnœa on the least exertion and albumin was present in the urine.

On March 1st the patient had an attack of enteritis lasting for a day or two but improving under treatment; this returned, however, on the 7th with the passage of a small quantity of blood and lasted till his death. The blood was more or less bright and the motions were offensive. Epistaxis was present during a part of each day. Some enlargement of the liver was noticed now. There was no pleural effusion and the optic discs were clear. On the 9th Dr. Hobhouse again saw the patient. β naphthol was suggested and oxygen, and owing to a request from his medical attendant in Morocco atoxyl was given in small doses subcutaneously. On the 11th œdema of the feet and ankles was present with small petechiæ scattered over the legs. The gums were bleeding continuously and the epistaxis and melæna continued. On the 12th the patient was in the same condition. One of the incisor teeth fell out and others were loose. The breath was very foul and he was drowsy. On the 13th and 14th there were continuous dyspnœa and cardiac dilatation. On the 15th the patient died during sleep.

Remarks by Dr. HOBHOUSE.—Acute lymphocythæmia is comparatively a rare disease. Out of 17,000 medical admissions at the Johns Hopkins Hospital, McCrae found that there were 13 of lymphatic leukæmia, of which five only were acute. Its genesis and many of the attendant conditions are obscure, so that it is desirable to record every case of the disease so far as it is known. The preceding case, which I twice had the pleasure of seeing with Mr. Scatliff, was in many ways a typical one and presents several features of interest. When I first saw the patient his condition in some respects suggested typhoid fever, in others an acute septic infection, but there was none of the depression usually associated with either. The patient felt well, did not look very ill, and thought he ought to be up, though his temperature was nearly 103° F. The condition of the gums resembled scurvy, as they were swollen and bleeding. His colour at that time did not suggest any blood dyscrasia, but this may have been partly due to the fact that he was seen by artificial light, as his friends say that they noticed some pallor in October. At my next visit (March 9th) the sallow hue was a very marked feature, closely resembling that of pernicious anæmia. The blood picture was fairly typical of what is usually found in the disease, but the number of polymorphonuclears was

---

[1] Cf. F. G. Bushnell: Structural Continuity in New Growths, Brit. Med. Jour., Dec. 1st, 1906; A Case of Generalised Sarcoma with Blood Changes (containing references on the subject), Transactions of the Pathological Society of Great Britain and Ireland. J. E. Farmer, J. E. S. Moore, and C. E. Walker: The Behaviour of Leucocytes in Malignant Growths, Transactions of the Pathological Society of London, 1905.



larger than is usually found when the disease is acute—viz., 18·0 per cent. Many of the large lymphocytes were granular and myelocytes were practically absent. Apart from the blood count, the hectic temperature, the hæmorrhage from the mucous membranes, the purpuric eruption (which may be general or local and is often the earliest symptom), and the moderate enlargement of the spleen and of the lymphatic glands constituted a striking clinical picture which once seen can hardly be missed. It may suggest in turn several diseases—typhoid fever, scurvy, purpura, and acute septicæmia—but is consistent with *none of them*. A blood examination even of the most superficial character will reveal the nature of the disease. It is only one more proof of the desirability of a blood examination in all doubtful cases. The age of the patient is also suggestive. As to the ultimate nature of the disease, whether it is due to an infection or whether it is really a lympho-sarcomatosis of the blood, we are at present in the dark; the evidence is fairly equally divided.

Two remarks may be made in conclusion. 1. That whatever explanation is offered it must be one which will embrace all forms of leukæmia, for every kind of transitional stage between the spleno-medullary and lymphatic forms is met with and they cannot be taken apart. 2. The parasitic theory is the only one which in the present state of our knowledge offers us any hope as regards treatment—viz., on vaccine lines—but it must not be forgotten, if organisms are found, that they may be only a terminal infection indicative of the special vulnerability of the tissues.

A DANGEROUS DRY SHAMPOO.

By HORACE C. COLMAN, M.D. EDIN.

With Additional Remarks by C. R. MARSHALL, M.A., M.D. Vict., *Professor of Materia Medica in the University of St. Andrews.*

A LADY was attended recently at her own house by a hairdresser for the purpose of cutting and dry shampooing her hair. The operation took place in a moderate sized bathroom with the window slightly open; the room was probably rather warm. After the cutting process was finished the lady placed her head over the basin in the usual fashion and the operator proceeded to pour some liquid over her head. At once she cried out that it was far too strong, and the man replied that it would soon pass off. Her next recollection is that of finding herself propped up on the floor, a wet towel round her head, the window wide open, and a very frightened hairdresser fanning her vigorously with a towel. She was informed that she had been unconscious for five minutes and had been a very nasty colour. Assistance was obtained and she was put to bed, where I saw her shortly after. She had vomited severely before my arrival and she told me that she felt just as she did after taking chloroform and her appearance tallied exactly with her description of her feelings. Her colour was bad and her pulse was somewhat accelerated; she had a severe headache and complained greatly of nausea. During the night she vomited once more, but in a day or two she was all right again and in her usual good health.

The hairdresser told her that the liquid used was tetrachloride of carbon and that he had used it eight times that week. On making inquiries of the man's employer I found that the drug is in frequent use for dry shampooing and that it came into use after a fatality with petrol in a barber's shop in London. I further found that in a shop it was the custom to use a form of apparatus to keep the vapour away from the customer's face, but that the "trade" seemed quite unaware of the dangerous nature of the liquid which appears to be in frequent use. The hairdresser gave me a bottle of the liquid as supplied to him and this Professor C. R. Marshall kindly undertook to examine. It is only necessary to read Professor Marshall's remarks, which he has allowed me to publish, to feel assured that what, happily, was only an extremely unpleasant experience for the lady might easily have ended in her death and that hairdressers will be well advised to seek some liquid less dangerous to use.

Remarks by Professor MARSHALL.—The liquid given me by Dr. Colman smelled strongly of commercial carbon disulphide, but on submitting it to fractional distillation it was found to consist of carbon tetrachloride, containing a trace of the impurities usually present in carbon disulphide and which give to it its unpleasant odour. No carbon disulphide itself was present in the liquid but some mixed perfume in alcohol had been added.

The symptoms described by Dr. Colman were certainly due to the inhalation of carbon tetrachloride. This substance was investigated in the "sixties" by Richardson, Simpson, Sansom, Nunneley, and others, and it was given by inhalation about that period for headache, neuralgia, chorea, &c. As it was found to produce decided ill-effects its use was abandoned. Since that time it has received very little attention from pharmacologists or clinicians. My own experiments, made nine years ago, are probably the most recent. In these I compared the action of chloroform and carbon tetrachloride, more particularly as regards their toxicity. The action of carbon tetrachloride was found to resemble that of chloroform, the differences being explicable to a large extent by differences in physical characters (vapour pressure, solubility in water, &c.). It is important to note that all observers have found carbon tetrachloride to be more toxic than chloroform. It is more irritant to mucous membranes and is much more depressant to the circulatory and respiratory systems. During its inhalation cardiac weakness and irregularity and cyanosis have been described and after the return of consciousness cardiac weakness, headache, and mental and bodily exhaustion have been noted. Anæsthesia is less easily produced and is slower in appearing than that by chloroform owing to the lower vapour pressure of carbon tetrachloride (boiling point of chloroform from 60° to 62° C., of carbon tetrachloride 76·5° C.), but it also disappears less quickly. It is probably owing to this relatively low vapour pressure that no fatalities have hitherto been described but it is obvious that such a dangerous substance should not be in the hands of hairdressers to use on all and sundry.

Broughty Ferry, N.B.

Clinical Notes:

MEDICAL, SURGICAL, OBSTETRICAL, AND THERAPEUTICAL.

A CASE OF TETANUS.

By D. LEIGHTON DAVIES, M.D., M.S. LOND.

THE patient, a healthy-looking farm labourer, aged 45 years, fell down on the road and sustained a cut over the right malar bone. The wound was not treated in any way and in the course of the next few days it kept "gathering and discharging." Six days later he felt his jaws becoming stiff and on the seventh day he was quite unable to open his mouth. When seen on the following day—i.e., eight days after the infliction of the wound—he was quite unable to move his lower jaw more than one-sixth of an inch. There was a suppurating wound over the right malar bone just below the outer margin of the orbit. From this a track passed beneath the skin for about one and a half inches into the cheek and this contained a quantity of yellow pus. No bare bone was felt. There was slight chemosis of the conjunctiva of the right eye. He was intelligent and, except for the trismus, complained of no pain. There was complete right facial paralysis, the furrows on the right side of the forehead and the naso-labial fold being obliterated. There was inability to close the right eye and the lower eyelid had fallen away from the globe of the eye. The mouth was drawn over to the left. Both masseter muscles felt firm, but could be made harder by voluntary effort. There was no spasticity or paralysis of any other muscles of the body, the neck muscles being quite normal. There was no loss of sensation anywhere. Both knee-jerks were brisk and the plantar reflex was flexor. His pulse was normal in rate and his temperature was 99° F. On the next day (i.e., the third day of the illness) laryngeal spasms developed. Sudden paroxysms of intense dyspnœa would occur from time to time, during which there was tremendous action of the platysma myoides, giving the face a very hideous expression. He became almost maniacal during these paroxysms, tearing the dressings off his head and throwing himself about violently, and all the while he was bathed with a profuse perspiration. There was no cyanosis even during an attack and the pulse was strong. The temperature remained normal. In the intervals between the paroxysms the neck appeared to be a little stiff. To allay the paroxysms he was given a quarter of a grain of morphine hypodermically and this gave him relief for over 12 hours. At the expiration of that time he suddenly became worse, jumped out of bed in a frenzy, and fell back dead. Unfortunately, a post-mortem examination was not permitted, but I succeeded in obtaining the trunk of the facial nerve of the right side as it left the stylo-mastoid foramen. To the naked eye it looked quite normal and microscopical examination showed an entire absence of pathological changes both in the neurilemma and the nerve fibres themselves.

Remarks.—The case was undoubtedly an example of infection with the tetanus bacillus, though at the time I overlooked the desirability of taking some of the pus for bacteriological examination. It differs, however, from the somewhat meagre description of this variety as given in the text-books I have consulted. The prognosis is stated to be somewhat more favourable in this variety than in the generalised type, but in this case death occurred three days from the onset of symptoms and nine days after the opportunity of infection occurred, and there was an entire absence of generalised spasm. There was no pharyngeal spasm but the laryngeal spasm was very distressing. The sudden termination of the disease in death may have been due to the laryngeal spasm or more probably to a sudden spasm of the cardiac muscle caused by the action of the toxin on the vagus centre. With regard to the underlying pathological changes leading to the facial paralysis, it has in the past been suggested that there was an ascending neuritis of the facial nerve. In the cases that have been examined no such changes have been found in the facial nerve and certainly there was no neuritis in this case. It is very probable that the paralysis is due to the action of an excessive dose of a virulent toxin on the nucleus of the facial nerve leading to the destruction of its cells. This is rendered more probable by the fact that the only muscles affected by the spasm were those which were innervated by nerves having their origin from nuclei in the neighbourhood of the seventh. The toxin must have reached the facial nucleus by passing up the lymphatics accompanying the facial nerve, for clearly it was not likely to have been the blood-stream, seeing the region picked out was so localised and definite. This fact, too, may explain why it was that the facial nerve was paralysed and the other nerves escaped, for it may be conjectured that the virulent toxin meeting first the cells of the facial nucleus destroyed them, and that by the combination of some of the toxin with the protoplasm of the cells, which is known to occur, the virulence of the toxin was diminished so that its action was merely irritating and not destructive on the remaining nuclei.

Wisbech.

CALCIUM SALTS AS A CARDIAC TONIC.

By JOSEPH STARK, L.R.C.P. & S. EDIN., L.F.P.S. GLASG

CALCIUM salts have come much into prominence of late in the treatment of ulcers, both internal and external; they are also advocated for chilblains and to be given before operations likely to be attended with severe hæmorrhage. The well-known therapeutic effect of calcium salts is that they increase the coagulability of the blood. It is therefore quite easily understood why they are given in cases where hæmorrhage is anticipated but in cases of cardiac disease and pneumonia I think that some reasoning is required before accepting the same. Having under my care a married woman, aged 40 years, suffering from an ulcer on one of her legs, which seemed to be due to deep varicosity of veins I gave her 15 grains of calcium chloride three time a day. At the time I did not further examine her as she was fully dressed. I was called out on the third day of treatment to see her—she was complaining of numbness of the right side of the body and was cyanotic. The next day she was a little better but still had the feeling of "pins and needles" in her right arm and leg. On the following day she had complete hemiplegia. There is no doubt on account of the slow onset that the lesion was due to cerebral thrombosis. I may state that I had now further examined the patient and found that she had a mitral lesion. I thought of my treatment and the therapeutic use of the same and came to the conclusion that the calcium salts had something to do with the condition of the patient. Sir James Barr has lately advocated calcium salts in pneumonia. It is well known that an ante-mortem clot is found in the pulmonary artery in most of the fatal cases of pneumonia. Then why should the practitioner endeavour to increase the coagulability of the blood? Dr. W. Blair Bell says that it is only in certain cases that we should use the same. I do not think that Dr. Bell's method of examining the blood is applicable in general practice and therefore I would advise general practitioners at least not to treat pneumonia and diseases of the heart by the calcium salts.

Annfield Plain, R.S.O., Durham.

HERNIA OF ILEUM PRESENTING OVER THE THORACIC WALL.

By HERCULES H. MACDONNELL, M.D. DUB.,
SURGEON, LOUTH COUNTY INFIRMARY.

A MAN, aged 28 years, was admitted into the Louth County Infirmary, Dundalk, on Oct. 8th, 1906. On the previous day he had been knocked off his bicycle. On admission he complained of faintness and pain over the chest, and a small tumour about two inches in diameter was seen situated over the sixth and seventh ribs on the left side about two and a half inches from the border of the sternum; this was extremely painful to the touch, so much so that a thorough examination without the aid of an anæsthetic was not possible; for several reasons it was not considered advisable to administer one. The skin over the tumour had a slightly bluish appearance. A tentative diagnosis of fractured ribs with a possible hæmatoma was made. Pads were placed at either side of the tumour to avoid pressure and a broad flannel roller applied over the thorax. The bowels were freely moved on the next day. On the fourth day after admission, on removing the pads and bandage to make a further examination, a superficial area of four inches broad was seen to be bright red and fluctuation was felt. The surface having been sterilised a free incision was made over a director, when an escape of gas and fæculent matter took place. A portion of intestine, doubled on itself, of the thickness of a thumb and gangrenous, was found lying in the wound; the tissues were undermined in every direction with fæculent matter. The bowel having been with some difficulty drawn up till a healthy portion was reached was divided, one end was sewn to the skin, and a thoroughly permeable fistula established. Owing to the patient's collapse and to the state of the tissues it was not deemed advisable to proceed then to further operative measures. As much of the gangrenous intestine as possible was removed. Subsequently rectal alimentation was carried out, which for a time succeeded extremely well, eventually enabling a little strong beef essence to be taken by the mouth, but after a week this had to be discontinued, as fæculent matter, discharged through the opening, brought on such an unhealthy condition of the integument and subjacent tissues. Small enemata of saline solution used for the purpose of maintaining the rectum in a healthy condition were passed through the thoracic wound, but the patient gradually became weaker. As soon as the tissues surrounding the fistula were brought into a tolerably healthy condition an end-to-end anastomosis with a Murphy's button was carried out; eight hours afterwards flatus and fæces were passed freely through the anus, but the patient gradually sank and died in about 24 hours. During the operation the track of the hernia was carefully traced by dissection; the bowel, a portion of the ileum, was seen to escape from the abdominal cavity at the extremity of the ninth rib, passing over the eighth rib, and had forced its passage up to the upper border of the sixth rib.

Medical Societies.

OPHTHALMOLOGICAL SOCIETY OF THE UNITED KINGDOM.

Congenital Night Blindness.—Subretinal Cysticercus.—Metastatic Tumour of Choroid.

A MEETING of this society was held on June 13th, Mr. PRIESTLEY SMITH, the President, being in the chair.

Mr. E. NETTLESHIP communicated a genealogy in which Congenital Stationary Night Blindness occurred in Nine Consecutive Generations during about 250 years. This disease, often hereditary, was less known than retinitis pigmentosa and its so-called unpigmented variety and, unlike them, did not progress. A great part of the present case was published by Cunier nearly 70 years ago and had been mentioned by many writers. But the nature of the disease was unknown until a year ago, when, at Mr. Nettleship's request, Professor Truc of Montpelier examined several living night-blind descendants, established the diagnosis, and instituted a fresh inquiry, resulting in an extension of Cunier's tables from upwards of 600 persons in seven generations, to nearly 1800 in ten generations. Only certain branches of this large tree, containing about 260 persons, bore the disease, and of this number just *one-half* (129) contained in 60 childships were affected. In half the affected childships (29) the proportion of diseased to healthy agreed with the Mendelian theory; others showed a near approach to agreement, and others again would conform if the dominance were supposed to have been reversed. About a quarter of the cases seemed inconsistent with Mendelism, but incompleteness of record doubtless accounted for some of these. The disease always passed from parent to child without a break, was rather commoner in females than males, did not lead to blindness, and was not accompanied by any other defects or peculiarities. It was not due to consanguinity; there were only two first cousin and seven second cousin marriages, and only one of these nine produced night-blind children. No ophthalmoscopic changes were noted.

Mr. L. WERNER (Dublin) showed a coloured ophthalmoscopic drawing, lantern slides, and microscopic sections of a Subretinal Cysticercus. The patient, a youth, aged 19 years, had noticed a failure of sight in the right eye for four months. The eye was normal in outward appearance and the tension was also normal, but in the fundus close to the optic disc was a large spherical projection covered by the retina and resembling an intraocular tumour. It presented a transparent, bluish-white appearance with a very delicate margin in some parts. The surface was smooth and marked with white connective tissue-like areas and a small portion was pigmented. A remarkable feature was the presence of a deep pit in the tumour and also an enormously dilated retinal vessel, which disappeared abruptly in the growth. The diagnosis was doubtful and the eye was removed. On examination it was found that the growth was an intra-retinal cyst, in which a cysticercus had been encapsuled. The pit seen in the growth with the ophthalmoscope was found to be due to a mass of granulation tissue, which divided the cyst into two cavities in the sections. It extended from the posterior to the anterior wall and by retraction of the latter produced a depression in it. The blood-supply of the granulation tissue was derived from the dilated vessel alluded to before. Mr. Werner stated that intra-retinal cysticerci were very rare, for of 29 cases anatomically examined only three were in the retina.

Mr. WHITEHEAD read notes of (1) a case of Metastatic Tumour of the Choroid. A mammary tumour, which had been present two years, was removed seven years ago. Recurrence took place in the scar and many metastatic tumours appeared in various parts of the body. Vision failed in the right eye and after four weeks the eye became blind and glaucoma set in. The eyeball was excised and a flat growth was present in the choroid. Microscopically this was found to consist of closely packed spindle-shaped cells with an excess of fibrous tissue between irregular groups of tumour cells. 2. A case of Multiple Cysts of the Retina associated with Glaucoma.

EDINBURGH MEDICO-CHIRURGICAL SOCIETY.

Exhibition of Specimens.—Administration of Gas and Ethyl Chloride.—Massage and Movement in the Treatment of Fractures.—The Naso pharynx as Infection Carrier in Epidemic Cerebro-spinal Meningitis.

A MEETING of this society was held on June 5th, Dr. J. O. AFFLECK, the President, being in the chair.

Dr. R. W. PHILIP showed a series of specimens from cases of Poisoning by Hydrochloric Acid.

Mr. WILLIAM GUY read a paper on the Administration of Gas and Ethyl Chloride. He said that, having administered anæsthetics to some 26,000 patients without mishap, without experiencing a moment's anxiety, or having to use a pair of tongue forceps or to practise artificial respiration, he might be allowed to express some confidence in his methods. He employed from time to time all the usual agents alone, in mixture, and in sequence, but his present practice was to use nitrous oxide for all operations that could be performed in 30 seconds, nitrous oxide and ether for operations requiring from one and a half to three and a half minutes, and nitrous oxide and ethyl chloride mixture for operations requiring from 30 to 90 seconds, this last class comprising the great majority of hospital extraction operations. He referred to "somnoform" and said that although it was unstable and expensive and had no advantages over ethyl chloride alone Dr. Rolland's researches in connexion with it were of great value in drawing attention to its constituents, particularly ethyl chloride. Ethyl cloride was at present under a cloud owing to the large number of deaths (30) recorded as attending its use and to its disagreeable after-effects. He quoted the opinions of authorities and said he had himself entirely given up the use of ethyl chloride by itself, because the mixture of gas and ethyl chloride was in every way preferable. The dangers of ethyl chloride anæsthesia were (1) direct cardiac inhibition; and (2) asphyxia from (*a*) partial or complete respiratory obstruction; and (*b*) paralysis of the respiratory centre by an overdose. The first danger was avoided by giving nitrous oxide to slight narcosis before ethyl chloride; the other dangers must be met by taking all precautions to eliminate the asphyxial element and by keeping the dose of the drug and the time of administration within the ascertained limits of safety. He described his apparatus and method of administration. He referred to the importance of not stretching the patient's neck. He used gags which were a slight modification of Hewitt's gags. He insisted on the gag always being placed centrally, never at the side of the mouth, and his gags therefore had horizontal instead of sloping surfaces. He rather advocated the use of a small centrally-placed gag as a routine procedure in anæsthesia, the ready access thus afforded to the mouth being of incalculable value in case of obstructive respiration. He used a one-gallon bag of gas, allowed the patient to rebreathe gas for five respirations, then poured in the ethyl chloride, the dose of which never exceeded three cubic centimetres, and allowed the mixture to be breathed and rebreathed for 25 seconds. By this practice wonderfully uniform results were obtained. The induction was pleasant, the recovery immediate, and after-effects were extremely rare. The residual air was sufficient to oxygenate the blood during the brief inhalation, consequently there was no cyanosis and with the dose limited to three cubic centimetres and the time of inhalation also limited there was no danger of an overdose. The temperature of the room should not be below 60° F. and the bag should be dry; the mixture was strictly a single dose anæsthetic and should never be used for long operations. He thought ethyl chloride would be rehabilitated in the eyes of the profession if its use alone were abandoned, if its limitations were recognised, and above all if it were given only in mixture with gas in a suitable apparatus and with a defined maximum of dose and time of inhalation never to be exceeded save by exceptionally experienced anæsthetists. His apparatus had been made for him by Messrs. Gardner and Son.—Dr. T. D. LUKE, Mr. J. H. GIBBS, and the PRESIDENT took part in the discussion which followed.

Mr. CHARLES W. CATHCART read a paper on the Use of Massage and Movement in the Treatment of Fractures. He said that with very few exceptions every fracture could have massage applied to it with much benefit to the patient. The methods of treating fractures which were universally accepted 20 years ago and which were still practised by perhaps the majority of surgeons were based upon the supposed necessity of absolute immobility of the broken ends of the bone until the callus was well formed. Immobility was a first principle and as a corollary the rule was that the apparatus which fixed the broken ends should also fix the joint above and the joint below. The period during which immobility was kept up varied from three weeks to three months or longer. After union the return of the limb to functional usefulness was taken into consideration but not before. It was then found that the weakness and stiffness of the muscles and the limited range of movements of the neighbouring joints often entailed more than double the period of functional disability of the injured limb and in many cases were permanent. These consequences were considered to be inevitable. The experience of Professor L. Championnière, Professor Guermonprez, and others in France, of Mr. A. G. Millér and others in Edinburgh, and of Sir William H. Bennett, Mr. Wharton P. Hood and others in London and elsewhere had shown that absolute immobility was not necessary. The following conclusions might be stated. 1. That absolute immobility was not essential to bony union; the slight movement involved in daily massage and in the daily practice of active and passive movements of the adjacent joints seemed to hasten the formation and solidification of the callus. 2. That extravasated blood in joints, muscles, and synovial sheaths led to adhesions as if it were a source of irritation. 3. That the use of massage in the form of stroking and gentle kneading combined with occasional movements was very beneficial not only in hastening union but in aiding absorption of effused blood and serum, and in preventing the formation of adhesions, and in maintaining nutrition of the muscles. By these means the limb was prepared to resume its functions almost as soon as the bones were united. 4. That splints and other retentive apparatus, including extension, were required more to prevent mal-union than non-union and were called for when the weight of the limb or muscular action might lead to bad position. The object of massage, given one or two hours after the accident, was to diminish the swelling, to allay muscular spasm, and to soothe pain after acute symptoms had subsided; massage stimulated circulation in the limb, dispersed accumulations of blood and serum, and maintained the nourishment of muscles, nerves, and soft parts. Massage must be applied without giving the patient pain. Active movements of muscles must be more effective in maintaining the nutrition of muscles and of the limb than passive movements but they were attended with a greater risk of displacing the ends of the bone. Thus passive movement was often permissible at an early stage and would be especially useful in preventing the formation of adhesions between muscles and nerves and the bones at the seat of fracture and within joints and synovial sheaths, while active movements would be of most value in keeping up the nutrition of the soft parts generally. Both forms of movement required to be used with care to avoid displacement of the broken ends of the bone. Splints were required to prevent deformity and to give support during the painful stage. These splints should not constrict the limb or hinder circulation and should not fix the neighbouring joints, so allowing occasional voluntary movements. The long splint should not now be employed in fractures of the femur (except in restless children or delirious adults) because fixation was not necessary and sandbags would prevent rotation. Splints might be of value in giving support as in Colles's fracture. Extension by weights or elastic cords was in some cases indispensable for obtaining apposition of the broken ends as was seen in oblique fracture of the femur where the continuous pull tired out the muscles, relieved spasm, and diminished or completely overcame the over-riding. The mistake often made was in continuing extension too long. It was seldom necessary to apply it for longer than three weeks and usually a much shorter time sufficed. In fracture of the clavicle a more rapid and equally satisfactory result was obtained by the use of the simple sling instead of the cumbrous appliances often used. The elbow might be supported for a few days merely to relieve discomfort but massage and movements of the muscles and joints sufficed to obtain a rapid union. In fractures of the humerus, unless there was great displacement, rest in bed without any appliance for the first few days and daily massage would conduce to early functional restoration. The deformity in a Colles's fracture must be reduced by extension and manipulation and mobility of the wrist and fingers must be conserved by massage and early movement. During the early days support was afforded by a splint and sling. Mr. Cathcart alluded to other fractures which should be treated in this way with advantage to the patient.—Mr. DAVID WALLACE, Mr. ALEXANDER MILES, Mr. J. W. DOWDEN, Mr. A. A. SCOT SKIRVING, Mr. GEORGE L. CHIENE, Dr. J. H. A. LAING, and Dr. A. D. WEBSTER took part in the discussion.

Dr. J. S. FRASER and Dr. J. D. COMRIE communicated a paper on the Naso-pharynx as Infection Carrier in Epidemic Cerebro-spinal Meningitis. Dr. Fraser said that the idea of carrying out this investigation in Leith was suggested to him by reading the papers of Dr. Ludwig Jehle on the Epidemiology of Cerebro-spinal Meningitis. He pointed out that school epidemics were unknown, that second cases in the same house were uncommon, and that cases of cerebro-spinal meningitis, which had been put into scarlet fever or other wards on a wrong diagnosis, did not give rise to further cases in these wards, and, finally, that meningococci were not found in the noses of these other children; he concludes, therefore, that cerebro-spinal meningitis was not like other infectious diseases in its mode of spread and that children might be excluded as infection bearers. On the other hand, he pointed out that coal-mines were good incubators, as in them they had heat, darkness, and moisture—all favourable to the growth of micro-organisms. *Miners also made good* infection carriers, as they frequently suffered from chronic rhinitis and pharyngitis and were in the habit of constantly hawking and spitting; they also used the same tools and drinking vessels in the *mines*; on the return of the miner to his home the children might become infected by kissing, using the same drinking vessels, or, in the case of very young children, by crawling about on the floor on which the fathers had expectorated. The table "Orlan-Karivics" showed the cases connected with the 16 *shafts of the mine* during the months of January till May. Five, eight, and 19 cases occurred in those families in which the fathers worked in certain shafts. The families themselves lived far away from one another, did not know each other, and had no contact with one another. Contact on top of the earth could not be proved. The connexion was, however, quite clear when they considered the mine or shaft; the miners infected one another during their work and carried the germs home to their families. In table "Neumühl" and "Deutscher Kaiser" the cases were divided according to the shafts. In almost all cases the disease affected the children of workmen belonging *to one shaft*. The children of other workmen from other shafts remained well though they lived in the neighbourhood of the sick children. With regard to coal mine "Neumühl" with two shafts and coal mine "Deutscher Kaiser" with four shafts, the miners lived in colonies belonging to these mines and also to some extent in private houses. Other workmen also lived in the colonies which were in close contact. The children from various colonies come together at school and play. In January, 1906, 23 cases occurred; the fathers of all of these worked in the Neumühl mine; there were no cases in the Deutscher Kaiser mine. After Feb. 1st, 1906, several miners came from the Neumühl to the Deutscher Kaiser mine and on Feb. 10th the first case occurred in a child of one of the miners of the Deutscher Kaiser. In the Neumühl epidemic the children of fathers working in certain shafts were quite free from disease; from other shafts a few cases occurred; and from others very many. The dwelling houses of the cases were quite separate. It was found that when miners were transferred from uninfected shafts of the Neumühl to the Deutscher Kaiser mine no cases occurred in the latter, but when they came from infected shafts such as No. 15 there was a serious outbreak among the children of the miners of the Deutscher Kaiser shaft to which these infected workmen had gone. The conclusion come to by Dr. Jehle was that in mining districts the coal mines played the same part as the school in the spread of other infectious diseases. With regard to epidemics of cerebro-spinal meningitis in garrisons, prisons, and workhouses the possibility of a naso-pharyngeal infection was not to be excluded; in fact, it was extremely likely. The following seaport towns had been affected by the present epidemic: Glasgow, Belfast, Leith, New York, New Orleans, Boston, Hamburg, Copenhagen, and Antwerp. Other cities have been affected, inland cities, but the number of seaports involved was certainly noteworthy; in regard to this it was at least possible that emigrants played a part in spreading the infection. As to the epidemic in Leith there had been 83 cases up to May 28th, 1907 (53 deaths). The connexion with the docks was very marked indeed, at any rate at the commencement; the social class affected was the lowest one—the casual labourers and their wives and children; the habits of this class as regards cleanliness were well known. He referred to the state of the houses visited, to the conditions under which meals were taken, and to the habit of hawking and spitting. Dr. Fraser suggested that in a ship below decks conditions to some extent resembling those in a coal mine were met with—darkness, moisture, and heat; the presence of coal dust in certain parts must not be forgotten. 80 per cent. of the patients in the Leith epidemic were under 16 years of age; this was just the age at which naso-pharyngeal catarrh was most common in connexion with the presence of adenoid growths in the naso-pharynx. The children themselves did not go down to the docks and if the epidemic had been connected with the docks it was almost certainly through the fathers. The investigation carried out was admittedly incomplete and was by no means free from difficulty. Dr. Fraser and Dr. Comrie had no compulsory powers and the parents and children were often frightened and refused to be examined. The secretion was withdrawn from the naso-pharynx by means of a long sterilised platinum loop, the nostril being dilated by a speculum and the greatest care being taken to avoid touching the speculum or the vestibule of the nose. The secretion was then smeared over the surface of a sloped blood agar or ascites agar tube and the tubes were all placed in the incubator within one hour of being taken. Disappointment was felt at not finding the organism in a higher percentage of the "contacts," especially of the fathers; it must be remembered, however, that only one loopful was taken from each case and probably it would have been better to have examined the fathers, at any rate, on several occasions. Of the 83 cases seven were double cases in one house. With regard to the prophylaxis, the fact that measures of this nature taken in other infectious diseases had proved useless in stopping an epidemic of cerebro-spinal meningitis went far to prove the unusual method of infection in this disease—shutting up the schools, removing the patient to an isolation hospital, and disinfection of the house and contents had practically no influence on the progress of the epidemic. If the theory of naso-pharyngeal infection through the fathers or others was the true one, it pointed to the necessity for isolation of all "contacts" and bacteriological examination of the nose and naso-pharynx. These cavities should subsequently be disinfected with very dilute formalin or with izal, boric lotion, silver nitrate, or potassium permanganate solution, or pyocyanase. Since Dr. Robertson introduced this antiseptic treatment of the "contacts" at Leith there had only been one second case in a family, and Dr. Fraser was informed that this patient was already feeling ill at the time when treatment was commenced. The "contacts" should only be allowed to leave the hospital after their noses had been reported to be free from the meningococcus on two consecutive occasions. The objections to this method of prophylaxis were, first of all, the expense of isolation and examination and probably also of compensation; and, secondly, the tendency to secrecy which such a course might involve.—Dr. COMRIE explained how the cultures were made on blood-film agar or ascitic agar. The meningococcus was found in the naso-pharynx of two out of 13 cases of epidemic cerebro-spinal meningitis examined. This small proportion was probably due to the extreme difficulty of isolating one organism from patients who were extremely ill and whose nasal cavities swarmed with many different forms. The organism was found in the naso-pharynx of ten out of 69 "contacts" with these and other cases. Of these ten five were fathers of the cases, and of the 69 "contacts" 15 were fathers of cases. While the organism was present in 9 per cent. of the mothers, brothers, sisters, and other relatives, it occurred in 33 per cent. of the fathers. Five of the 15 fathers worked in a ship in the dry dock and in exposing Petri dishes containing ascitic agar in various parts of this ship below decks the meningococcus was found in the air of the engine-room. The naso-pharynx was examined in 23 controls who had no evident connexion with the disease and the organism was not found in any of them.

EDINBURGH OBSTETRICAL SOCIETY.

Vaginal Cæsarean Section.—Congenital Goitre after Administration of Potassium Iodide to the Mother.

A MEETING of this society was held on June 12th, Dr. J. W. BALLANTYNE, the President, being in the chair.

Dr. N. T. BREWIS read notes of Six Cases of Vaginal Cæsarean Section. The first patient was operated on for severe and intractable vomiting; she was in the fifth month of pregnancy and owing to the vomiting had been brought to a condition of extreme danger. The operation was performed in the patient's house without any special preparation and was successful in every way. The second patient was seven and a half months pregnant; the urine was loaded with albumin and her feet were swollen. She complained of headache, was stupid, and at times only half conscious, while on the day previous to the operation she was more or less comatose and had only passed a very small quantity of urine which solidified on boiling. At the operation a living child was delivered who survived after much care with the aid of an incubator. The mother recovered after passing through an attack of broncho-pneumonia. Dr. Brewis preferred the operation to that of the classical Cæsarean section as being simpler, safer, and more quickly performed. The operation was performed at full time in the third patient for stenosis of the os following amputation of a hypertrophied cervix. The child was born alive and the mother made a good recovery. The fourth patient suffered from mitral stenosis and incompetence with œdema of the lungs. She suffered greatly from breathlessness with heart pain and insomnia; her condition was very critical. The termination of the pregnancy was urgently indicated and Dührssen's operation was adopted as one calculated to cause the least strain to the heart. The result was most satisfactory, the patient being able to lie down and to rest comfortably on the third day after the operation. The indication in the fifth case was hæmorrhage caused by premature detachment of a portion of a placenta prævia; floodings had occurred at intervals. The patient was about six months pregnant and at the time of the operation was blanched and in a state of extreme weakness. After transfusion was performed vaginal Cæsarean section was done and the uterus was emptied. The patient recovered. The sixth case was one of continuous hæmorrhage in a patient two and a half months pregnant. Though the uterus might have been emptied by other means Dr. Brewis preferred Dührssen's method because it could be carried out more quickly and conveniently than by any other procedure. All the mothers recovered. Dr. Brewis said he considered that whenever the element of time was of importance vaginal Cæsarean section was a valuable addition to their resources. An operation which enabled them to pass the hand with safety into the interior of the uterus in a couple of minutes was one that might reasonably have its indications extended. It should not be restricted to cases of a serious nature but might be applied to all cases where the operation could accomplish its object more easily and conveniently than any other. It was an operation which appealed strongly to anyone with surgical instincts and those who had had experience of it could not do otherwise than commend it.—Dr. J. LAMOND LACKIE, Dr. J. HAIG FERGUSON, and the PRESIDENT made remarks on the paper, and Dr. BREWIS replied.

Dr. B. P. WATSON read a paper on Congenital Goitre occurring after potassium iodide had been administered to the mother during pregnancy. The mother had suffered from syphilis and had had five miscarriages, two at the third month and three at the seventh month. During the three succeeding pregnancies she was treated with potassium iodide and carried two of the children to full time. The second of the children had at birth a large goitre which gradually decreased in size till the child's death from an intercurrent disease at the age of three and a half months. Histological examination showed the goitre to be of the parenchymatous variety. Four cases were mentioned where congenital goitre followed the administration of potassium iodide to the mother during pregancy and one where both the chlorate and iodide had been given.—The paper was discussed by Dr. JAMES RITCHIE, Dr. H. O. NICHOLSON, Dr. G. KEPPIE PATERSON, Dr. FERGUSON, and the PRESIDENT, and Dr. WATSON replied.

BRITISH GYNÆCOLOGICAL SOCIETY.—A meeting of this society was held on June 13th, Mr. W. D. Spanton, the President, being in the chair. The following motion was adopted:—

> That we, the Fellows of the British Gynæcological Society, desire to express our feelings of deep regret at the loss the society has sustained through the death of our Honorary President, Dr. Robert Barnes.

Mr. A. W. Mayo Robson gave an address on the Modern Treatment of General Peritonitis and said he wished to bring the subject forward in a general way from the point of view of pelvic as well as of general surgery. He advised early operation and if undertaken within 12 hours of the onset this ought to result in saving the patient; if within 24 hours there was a probability that the patient's life would be saved; but if later there was only a chance of doing so. As short an operation should be done as possible without any damage to the viscera. If the cause were discovered it ought to be removed. Sponging and washing should be avoided but as much pus should be removed as could be done conveniently. After injection of as much fluid as possible either by the rectum or transfusion the patient should be propped up in a sitting posture in order that the septic fluid might gravitate to the lowest part of the abdomen and so be drained away readily. —Sir W. J. Sinclair recommended morphine and large doses of alcohol combined with flushing of the abdomen with saline solution, and considered if puerperal patients were watched and treated well they would not get peritonitis.—Mr. Charles Ryall believed the best form of drainage was by absorption and this was obtained by free action of the bowels.—Dr. Heywood Smith said large doses of calomel gave excellent results in the prevention of peritonitis.—Mr. Alban H. G. Doran said there was a great deal more to be learned about peritonitis and the best principle on which to act was to avoid it. The treatment with opium was of questionable utility.—Dr. Bedford Fenwick found the sitting posture useful when there was a difficulty in getting the bowels to act. He urged the avoidance of drainage and flushing.—Dr. H. M. Macnaughton-Jones advised the application of ice to the abdomen on the first appearance of symptoms. He preferred small doses of calomel to large ones. The most important question was whether the abdomen ought to be opened early or whether the symptoms only should be treated. He advised subclavian or submammary infusion in preference to rectal injections.—Dr. J. H. Dauber considered that the real hope for the future lay in the antitoxin method of treatment.—Dr. W. H. Slimon, Dr. H. Beckett-Overy, and the President also spoke and Mr. Robson replied.

Reviews and Notices of Books.

Alcohol and the Human Body. By Sir VICTOR HORSLEY, F.R.S., &c., and MARY D. STURGE, M.D. Lond. With a Chapter by ARTHUR NEWSHOLME, M.D. Lond., Medical Officer of Health of Brighton. With 14 plates and 21 illustrations in the text. London: Macmillan and Co. 1907. Pp. 370.

THE literature already published in reference to alcohol is so voluminous that it might be doubted whether any new book was necessary or could be expected to settle once and for all this much-debated subject. The prominence recently given to the question in medical circles and the scientific eminence of the principal author of the present work will, however, doubtless secure for it a wide circle of readers. The book is not specially addressed to the medical profession but to the public at large and is commendably free from technical expressions. The descriptions of the cells of the body, of the various tissues, and especially of nervous structures, as well as of the different functions which the organs discharge are given in simple language which the lay reader will have no difficulty in grappling with.

Sir Victor Horsley's views on alcohol are fairly well known; his platform utterances have led most to regard him as an extremist; but in the book before us extravagant language is conspicuous by its absence and its conclusions gain rather than lose thereby. We are, of course, in thorough agreement with those portions of the book which are directed against the misuse rather than the use of alcoholic beverages. There is no truer friend of temperance than the medical man. But the list of ailments due to alcoholic excess may surprise even the medical reader by its length, just as the list of maladies which advertisers proclaim their patent nostrums are good for is also portentously and impressively long. There is no pill which is a universal panacea for all human ills and there is no single cause to which nearly every illness can be attributed. The evils due to excess of alcohol are real and numerous and it is almost a truism to say that the nation's health and morals would improve if the immoderate use of intoxicating liquor was stopped. The change for the better which has already occurred is partly due to the gradual evolution of the moral sense of the people; still, we do not minimise the efforts of the teetotal party. Every great reform has had its enthusiasts and its fanatics. It is often only the fanatic who can obtain the ear of the people; too often they are deaf to the more reasoned voice of the accurate thinkers who can see both sides to a question.

Alcohol is not taken as a food; its combustion in the body may liberate a certain amount of heat and energy, but it is not for this reason that people take it. We may also freely admit that it is a poison and in sufficient doses a dangerous poison. We should not hesitate to prescribe teetotalism to those unable to restrain their appetites, to those who have an inherited or other taint in the direction of want of nervous control, and to those whose limited income should make them hesitate to spend their money in indulgences. But it is a very different thing to recommend universal abstinence from alcoholic drink. The tendency of medical practice has been to lessen materially the employment of alcohol as a drug in recent years; still, we doubt whether many practitioners would care to be altogether without it in emergencies. To expunge alcohol from the Pharmacopœia because it is a poison would be only the first step in excluding many other useful drugs for a precisely similar reason. It is hardly necessary to point out that the use of a poison as a drug is a question of dose and that another factor in its employment is the presence of abnormal conditions of the body. Sir Victor Horsley and Dr. Mary

Sturge see this in reference to other drugs; still it is only in the case of alcohol that they recommend its complete or all but complete disappearance. What they say about tea forms a useful illustration of the logical attitude. On p. 108 they quote with approval from Dr. T. S. Clouston the following sentence: "Its use *in moderate quantity* is not followed by any injurious reaction and is not prejudicial *to any of the functions of the body*." (The italics are ours.) Again on p. 213 we read: "Tea and coffee were also proved to retard gastric digestion; but the author (Sir W. Roberts) gives no report concerning the effect of those weak infusions of tea which have lately come into vogue, and which are little more than hot water."

It is, of course, both with regard to tea and alcohol a question of dose, the question of what is moderate drinking being the one on which the opponents of Sir Victor Horsley's views will join issue with him. No one wishes to dispute his conclusions regarding the immoderate drinker. It is very difficult to define accurately the word "moderate," and those who have even the slightest tendency to overstep the boundary would be safer if they became abstainers. But to suppose that the man who takes a glass of beer with his unch or a glass of claret with his dinner is materially njuring his health and morals or shortening his life is contrary to common sense and everyday experience. We ind in the chapter which Dr. Newsholme contributes the usual statistical argument derived from insurance offices. Thus we find that of every 100,000 total abstainers 45,000 die before *they reach the age of 70 years*; and of non-abstainers 56,000 die before that age. Dr. Newsholme admits that the non-abstainers include a proportion of drunkards (and we would add of immoderate drinkers who may not be *actually drunkards*) and yet he sums up: "We are compelled to conclude that what is commonly described as moderate drinking has a most injurious influence *on health* and life." Our own conclusion would be that statistics comparing the length of life between abstainers and really moderate drinkers are still lacking.

Some of the arguments directed against moderate drinking savour somewhat of the special pleader; thus the use of the ergographic method of estimating the onset of fatigue is decried because of its uncertainty. The old ergograph of Mosso doubtless lent itself to this objection, but the greatly improved form lately used by Dr. W. H. Rivers, especially when employed on subjects who are totally unaware of what drug they have received, is almost entirely free from the exercise of any bias, intentional or otherwise; it is strange that no reference is made to Dr. Rivers's researches. Kraepelin's work is naturally quoted at some length. This observer showed that small doses of alcohol will diminish the rate at which such operations as arithmetical problems can be performed. The duration of the impairment is estimated by an investigation which showed that the effect of a single dose taken in the evening may persist until the morning and noon of the next day. Kürz's experiments upon himself are also quoted under the heading "Duration of Effect of Small Doses of Alcohol." But this observer consumed 80 grammes (or 100 cubic centimetres) of alcohol in water on 12 consecutive days, and 80 grammes of alcohol measure three and a half ounces, which is equivalent to seven ounces of brandy or one and a half pints of port wine. No wonder that he felt the effects even till the fifth day of abstinence, but this is no argument against moderate drinking.

On p. 214 Chittenden's experiments are referred to. Chittenden found that when the percentage of alcohol in a digestive mixture was as low as 1 or 2 per cent. there was sometimes a slight acceleration of the rate of digestion, and that retardation is not very pronounced until the mixture contains from 6 to 10 per cent. or more of absolute alcohol. The conclusion most people would draw from this is that digestion is not retarded until the ingestion of alcohol has largely exceeded the "moderate" limit. But Sir Victor Horsley and Dr. Sturge draw the sweeping conclusion that all forms of alcoholic beverages *seriously retard the chemical process of gastric digestion*. They return to this again two pages later, when they say: "Many persons resort to alcoholic drinks at meal times in order that the flow of gastric juice may be increased. *Unfortunately, in addition to the moderate* increase of secretion of gastric juice a stimulation of the flow of mucus also occurs, which lies like a slime upon the internal surface of the stomach. This mucus is liable to hinder whatever normal absorption occurs from the stomach walls and leads, as aforesaid, to fermentation and production of wind in the stomach." We can imagine such an argument having weight with some people, particularly as it contains words, such as slime and wind, which they can understand, and if it induces a heavy drinker to reform the end may justify the means. We are not, however, acquainted with any researches which have shown that a dose of wine sufficiently moderate to cause an increased flow of gastric juice will produce such an alarming increase of mucus, and still less are we acquainted with the *modus operandi* by which mucus brings about fermentation.

We have been present at teetotal lectures where the lecturer has produced a brain or a liver hardened in spirit like a museum specimen in order to impress upon his audience the terrible effect of alcohol. If the organ had been kept the same length of time in the teetotaler's favourite beverage the effect upon it would have been still more disastrous. On one occasion a lecturer boiled some port wine in a flask and set light to the alcohol which issued from its mouth, saying "that is the terrible stuff you are burning your interior with." It is hardly necessary to say that the present authors do not stoop to follies such as these. We are therefore surprised to find them quoting Dr. J. J. Ridge's well-known unsuccessful attempt to grow cress and geraniums in solutions of alcohol. As well might the anti-water drinker quote Dr. S. Ringer's experiments on the harmful effects of distilled water on micro-organisms and tadpoles. We wonder what would happen to cress and geraniums if an attempt were made to rear them in a solution of caffeine or any other poison. Sir Victor Horsley might retort that caffeine is not tea or coffee, to which we can only reply neither is alcohol the sole constituent of wines, beers, and spirits as usually consumed. The authors certainly protest, and rightfully protest, against the shameful adulterations which are practised in the liquor trade and which have at times been shown to be responsible for effects previously attributed to alcohol but they take no heed at all of the action beneficial or otherwise of the ethers and other substances present in such liquors as old brandy, rum, burgundy, and champagnes.

The book, as we said at the outset, does not really settle the matter, except on points which were previously settled, such as the folly and wickedness of over-indulgence. It only raises the old controversies, sometimes in a way different from that adopted by previous authors, and all we have attempted to do is to point out how slender after all is the evidence that any serious result follows true temperance as opposed to total abstinence.

Text book on Diseases of the Heart. By GRAHAM STEELL, M.D. Edin., F.R.C.P. Lond., Senior Physician to the Manchester Royal Infirmary. Manchester: At the University Press. 1906. Pp. 389. Price 7*s.* 6*d.* net.

THIS volume forms No. VII. of the "Medical Series" published by the University of Manchester and fully maintains the high standard reached by its predecessors. Dr. Steell has aimed at giving an accurate account of the clinical aspect of heart disease, together with a description of the principles of the treatment of the disease. He has admirably succeeded in his endeavours. The book is published at a time when, as the author remarks in his preface, there is an immediate prospect of a great advance in our knowledge of the anatomy, physiology, and pathology of the heart, which promises to lead to much improvement in the application of available remedies. The lines along which this knowledge has recently progressed, and is likely in the future to progress, are duly indicated, and the work of Dr. James Mackenzie and Professor Wenckebach has been especially drawn upon for the purpose. Dr. Steell very properly awards great credit to Dr. Mackenzie for having demonstrated by mechanical means the nature of movements of the circulatory system, as, without such methods, these matters would have caused endless controversy, an instance in question being the pulsation which occurs in veins.

The portions of this volume which will probably attract the greatest attention are those dealing with mitral regurgitation and mitral stenosis. Dr. Steell adopts a different view in the matter of mitral regurgitation from those hitherto maintained by most writers. His remarks deserve close consideration, as they have an important bearing not only on the pathology of cardiac affections but also on their treatment. He rightly points out that in the case of the mitral valve apparatus a vital contractile element has to be reckoned with. No mitral valves, he says, are competent without the assistance of the heart muscle. Muscle contraction is a necessary complement of the mitral valve apparatus. He then proceeds to argue, and doubtless quite correctly so, that in a very large number of cases of mitral incompetence there is no structural disease of the valves; he maintains that they are rendered incompetent only on account of their failing to receive in the performance of their function the assistance from the heart muscle to which physiologically they are entitled. Further, he reminds his readers that for the perfect function of the mitral valve apparatus muscle contraction is necessary in two ways; it diminishes the orifice to be closed by the valves, and by shortening the musculi papillares it keeps taut the spread-out curtains. Dr. Steell is of opinion that in an "enormous number" of cases of mitral incompetence the incompetence is due to failure of the heart muscle only and is independent of any structural change in the curtains of the valves themselves. He then proceeds to discuss the effects of rheumatic endocarditis, and his conclusions will be found most interesting, though scarcely in accord with the views generally held on that subject. He naturally describes rheumatic endocarditis as being the great source of chronic valvular lesions, but maintains that stenosis of the mitral orifice is the result of such mischief in the majority of cases; in other words, that stenosis of the mitral valve is the principal lesion associated with rheumatism. From what we have stated above as to Dr. Steell's views it is not surprising to find this sentence added: "Mitral incompetence is no necessary indication of mitral disease at all."

It follows from these pathological considerations that if Dr. Steell's arguments are correct the physical signs which are usually taken as being diagnostic of mitral stenosis must be reconsidered. In most text-books it is taught that a systolic murmur heard over the apex of the heart is indicative of mitral regurgitation, whilst an apical diastolic or presystolic murmur indicates mitral stenosis. From a statistical inquiry as to the frequency of the different auscultatory signs of mitral stenosis founded on 60 cases, Dr. Steell found that a "systolic murmur in the mitral area" was the most common murmur, occurring in 75 per cent. A presystolic murmur occurred in only 53·33 per cent. of the cases, whilst a diastolic murmur, audible at the apex and above the apex, occurred in 66·66 per cent. of the cases.

We have perused Dr. Steell's work with much interest and can cordially recommend it as being full not only of original thought but of practical knowledge and utility. He states his views with confidence and this tends to carry conviction to the reader. We believe that he has a sound basis for his arguments and that on pathological, as well as theoretical grounds, there are many who will support him in the views which he advances on cardiac affections, more particularly in connexion with disorders of the valves of the heart.

The work concludes with an "appendix" on "The Volume of the Blood in Relation to Heart Disease," by Dr. J. Lorrain Smith, professor of pathology at the University of Manchester.

The History of the Wine Trade in England. By ANDRÉ L. SIMON, F.R Hist.S. Vol. I. London: Wyman and Sons, Limited. 1906. Pp. 387.

THE history of wine is very much bound up with the history of nations and it is chiefly this fact, we think, which makes this book interesting reading. The author expresses the belief that if a better knowledge of the history of wine in this country was acquired by the public a greater appreciation of the virtues of wine would be promoted, the more general use of which "would help to check both drunkenness and teetotalism, evils which every fair-minded and temperate man cannot help deploring." We are by no means certain that this view is correct. Nobody wishes to exterminate the teetotaler, because, after all, he is on the safe side and his error is merely zeal, while everybody would like to see sobriety the rule amongst the people. The story does not teach us that sobriety was the rule even before the days of spirituous liquors and, indeed, the classical instances of drunkenness and alcoholic debauchery were of course due to excessive wine-drinking. The teetotal reader who knows his history must realise that wine has on frequent occasions contributed to the gaiety of nations and gaiety in his mind means the prelude to debauchery and wantonness. It seems to us that a knowledge of the history of the wine trade and at the same time of the drinking habits of the people at various times is calculated to furnish him with a justification for his attitude rather than a condemnation of it. On the other hand, the reader who knows already the subtle influence of wine over his mind and body may be led to continue, if he does not increase, his indulgence of it by the fact of his interest being keenly aroused in all that appertains to its history and production. We see, however, and can appreciate the author's meaning. It is not difficult to read between the lines that his view is that wine-drinking—and we must assume that good sound wine is understood—encourages temperance, as against the drinking of ardent spirits. If that is his view we quite agree. It may be called to mind that spirits approach the character of pure alcohol, and unquestionably the purer alcohol is—that is, the more it is dissociated from other things—the more powerful is its physiological effect. It is a very common mistake to suppose that wine is merely a mixture of alcohol and water; it is not so simple. On the other hand, it is a very complex liquid and it is this complexity which profoundly influences or modifies the action of the alcohol contained in it. In speaking therefore of the physiological action of wines we ought to bear in mind that besides alcohol they contain tartaric acid, ethers, glycerine, tannin, and other substances. The effect of alcohol taken, on the one hand, with food and, on the other, on an empty stomach is acknowledged to be different, and surely the presence of acids, ethers, and astringents must modify its action also.

Mr. Simon must have spent a good deal of energy and time in the compilation of the very interesting historic facts contained in his book and we are sure that the work will appeal to a numerous *clientèle*.

LIBRARY TABLE.

A Last Ramble in the Classics. By HUGH E. P. PLATT. *Oxford: B. H. Blackwell; London: Simpkin and Marshall.* 1906. Pp. 208. Price 3*s.* 6*d.* net.—Readers of Mr. Platt's former delightful little work, "Byways in the Classics," will derive equal pleasure from this his second essay, which, despite the title, we hope will not be the last. Medical men will be particularly interested in this little book, though, unfortunately, they have as a rule but scant leisure to cultivate the classics, and notwithstanding Mr. Platt's rather unkind suggestion that they are prone to display weakness about quantities. But those of our readers who, amid hard work and scanty pay, like the famous coterie in Edinburgh, "*Musam tenui meditantur avena,*" will find charms in Mr. Platt's collection, though the allusions to medical practice in classical times make it appear that the physician and the surgeon were not always the subject of compliment. Martial wrote many rude epigrams upon physicians, and they were not among his best, but Juvenal, in his invective against the "smart set" of his day, is on the side of orthodox medicine when he narrates how the fashionable Roman lady preferred an Egyptian astrologer to the physician. For "astrologer" read "quack," or "hair specialist," or "health culturist," and the same is true to-day. It will be news to many that the Laws of the Twelve Tables, promulgated in 450 B.C. by the Decemvirs, contained a clause in which gold used for stopping a tooth might lawfully be thrown on the funeral pile. This shows how ancient a custom is the stopping of a tooth with gold, and also indicates that gold at that date was very rare among the Romans so that even a minute waste of it had to be legalised specially. It may be remembered that "Byways in the Classics" was made amusing by a selection of "mottoes" or sentences selected from the classics with an eye, and a very humorous eye, upon their application to phases of modern life. The following motto for golfers—and medical golfers are many—may have remained in the recollection of some: "*Miscueruntque herbas et non innoxia verba.*" "A Last Ramble in the Classics" (and again we beg that it may not be the last) contains a further instalment of "mottoes," of which we select the following two for quotation as of special interest to our readers: "For the fee in respect of a fashionable operation—*Appendices maioris muneris.*" "For a country town—*O colonia quae cupis ponte ludere longo!*" The second was sent to Mr. Platt by a medical man, Mr. A. Maude of Westerham. Mr. Platt gives well-earned praise to Mr. E. A. Eade who has suggested various singularly happy applications of the classics, notably the slightly altered Horatian motto for the dripping motor 'bus—"*Cujus odorem olei nequeas perferre ...... Callibus instillat.*" A chapter on melodious verse quotes Dr. Johnson's opinion on the subject. Dr. Johnson chose the fifth line of the first eclogue as an example of the most melodious verse—"*Formosam resonare doces Amaryllida sylvas.*" In our opinion the last line of the same eclogue has a music in it which few other lines, even in Virgil, have: "*Maioresque cadunt altis de montibus umbrae.*" There is a line by one who took Virgil for his master and guide which may fitly stand alongside this, and that is, "*Che paia il giorno pianger che si muore.*" On p. 169 Mr. Platt quotes a curious old Latin puzzle in the form of an epitaph copied from a tomb in Munich. There are, as he says, plenty of similar puzzles and their solution is very easy. We wonder if Mr. Platt has ever exercised his ingenuity upon the well-known sepulchral enigma commencing "Aelia Loelia Crispis." If he has, or if Mr. Eade has, we should like to hear the solution. In the section entitled "Some Questions suggested by Reading the Classics," Mr. Platt raises the point as to how the ancients managed to destroy a body by fire upon the funeral pyre, while it requires in our country, as he says, "an elaborate apparatus and an extraordinary degree of heat to cremate a human body." He has forgotten, we think, to allow for time. It must be remembered that in a modern crematorium a body has to be reduced to ashes in about two hours; hence the elaborate methods; a classical burning might take as long as the operators liked. The pyre of Hector apparently burned for 24 hours. We may point out also, in reference to a quotation from Tibullus, that a cremated bone retains its shape, though it becomes remarkably brittle and light. A body placed on the top of a pile of wood well soaked in oil and lighted from the bottom would soon be consumed—i.e., reduced to bone salts. For the middle of the pile would sink in and allow the body to sink in too, so that it would be "jacketed" with fire. As to the passage Juv. I., 157, a body just frizzled, as is implied by the previous lines, would only be charred superficially and there would be quite enough left to make a "latum sulcum." We owe a debt of gratitude to Mr. Platt for a most interesting little book.

The Principles of Qualitative Analysis. By WILLIAM BÖTTGER, *privat-docent* in the University of Leipzig. Translated with the author's sanction and revised with his coöperation by WILLIAM GABB SMEATON, Instructor in General Chemistry in the University of Michigan. London: Rebman, Limited. 1906. Pp. 300. Price 9*s.* net.—Those who are keeping in touch with the extraordinary developments of chemical science might have anticipated the publication sooner or later of a work on qualitative analysis presented in the light of modern conceptions. The theory of electrolytic dissociation and the law of mass action are constantly in evidence in connexion with the principles of qualitative analysis, and the only scientific method of representing the reactions concerned is by explaining the laws governing these changes. Time was, and not so very long ago, when we were taught simply that on adding hydrochloric acid to silver nitrate a double decomposition took place, a precipitate of silver chloride was formed, and nitric acid would be found in solution. In the light of the dissociation theory the explanation is that first of all silver chloride is composed of the "cation" Ag and the "anion" Cl. This union of "ions" is an insoluble compound, so that if a white precipitate is produced on adding hydrochloric acid to a soluble silver salt—e.g., silver nitrate—the inference is that the "cation" Ag is present. Conversely, if on adding a soluble silver salt to a solution a white precipitate is obtained the presence of the "anion" Cl is demonstrated. Silver nitrate is thus a reagent for the detection of the "anion" Cl, but silver nitrate is not a reagent for the *element* chlorine, since no precipitate is formed when it is added to potassium chlorate and in this case the solution contains the "anion" ClO_3 and not Cl. In short, in the performance of analysis most reactions in solution are reactions of the ions (cathions, positively charged ions, and anions, negatively charged ions), and in so-called double decomposition it is the ions which react and not the molecules. Herein is the scientific method of presenting the principles of analysis upon which this book is chiefly based. It is a beautiful working hypothesis and the author may be congratulated on the way in which he has succeeded in making clear these principles as applied to practical chemistry; moreover, the translator has accomplished his share of the work most creditably. The publication of such a work bids fair to displace entirely the commonplace text-book of analysis of which there is, or was, no end.

Sewage and the Bacterial Purification of Sewage. By SAMUEL RIDEAL, D.Sc. Lond. Third edition. London: The Sanitary Publishing Company, Limited. 1906. Pp. 355. Price 16*s.*—Nearly seven years ago we recognised in these columns the value of this work, and the call for a third edition endorses the view which we then took that

Dr. Rideal's contribution on the subject would be widely appreciated. The work is essentially practical and a guide alike to the chemist and to the engineer. The student will learn from its pages the *rationale* of modern methods for the disposal of sewage, he will realise what an important rôle micro-organisms play in these methods, he will also understand the relations existing between non-pathogenic and pathogenic organisms, and lastly he may acquire a knowledge of those practical chemical and bacteriological methods of analysis the results of which enable us to judge whether a given process is or is not working efficiently. From time to time the Royal Commission on Sewage Disposal has issued valuable interim reports but its final report which, it may be anticipated, will settle many questions of great importance to local authorities has not yet been issued. Dr. Rideal has taken advantage in the third edition of his book of the further experience which has been gained in regard to the bacterial methods of sewage purification during recent years, and this experience obviously includes the important conclusions of the Royal Commission so far as they have been published. This alone is a valuable feature of the book. It is to be hoped that every facility will soon be afforded to local authorities to enable them to develop methods of sewage disposal along the scientific lines indicated by recent developments. Dr. Rideal may be thanked for keeping his readers in touch with these developments and for the share which he has taken in helping to bring about a desirable consummation.

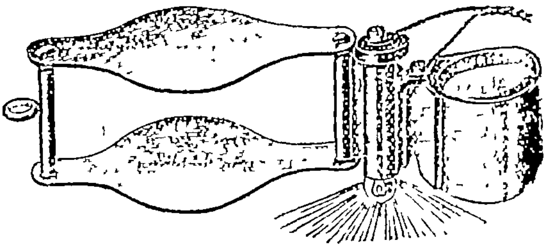
JOURNALS AND MAGAZINES.

The Journal of Nervous and Mental Diseases (April and May).—These numbers contain amongst other matter an interesting article on the Diagnostic Value of Lumbar Puncture in Psychiatry by Dr. J. L. Pomeroy, of Ward's Island, New York City. In making his investigation the method of technique described by Widal and Ravant was followed as closely as possible. In addition to this examination for lymphocytosis Dr. Pomeroy also advises that the albumin test should be made, as a case may show a positive albumin content even before lymphocytosis is discovered. He goes on to say that the usual presence of a large albumin content in general paralysis is of value and he advises caution in interpreting small augmentation of cells without previously examining the amount of albumin. He points out the diagnostic value of lumbar puncture in cases of congenital syphilis in which there is arrested development. On the other hand, he considers that a negative finding in a case with a syphilitic history is almost certain evidence that there is no involvement of the central nervous tissue, and in cases where syphilis of the brain is clinically to be diagnosed a persistent negative lumbar puncture should make the observer look for some other etiological factor. The figures that he gives of the results of spinal puncture in cases of paresis are as follows: in 30 undoubtedly clear cases (clinically), in every instance positive results were obtained and the albumin content showed a marked opalescence in every examination. In all cases the pressure was quite marked, the fluid spurting from the canal. Dr. Pomeroy considers that lymphocytosis is one of the earliest and most constant signs of paresis, and, according to Jaffroy, Marie, and Duflos, it appears before amnesic, ophthalmic, or ataxic symptoms. Further, the importance of repeated puncture is emphasised by Archard who records a case in which the first two punctures were negative, a third showed slight cellular increase, and finally a fourth gave a large number of lymphocytes. In this case an interval of ten days was allowed between each puncture. Dr. Pomeroy also alludes to the value of lumbar puncture in assisting the diagnosis in those difficult cases of chronic alcoholism in which there has been a previous history of syphilis. The article is concluded in the May number of the journal and after giving several more instances of the value of lumbar puncture from the diagnostic standpoint Dr. Pomeroy sums up his results as follows: 1. Lumbar puncture should not be resorted to unless the patient can be put to bed. 2. To be of definite value the procedure must be repeated two or more times at an interval of at least ten days. 3. A constant negative finding is of more value than a positive one, for it rules out the presence of syphilis of the brain and parasyphilitic conditions. 4. In general paralysis the lymphocytosis is a constant and early sign and is usually associated with a heightened albumin content. The same may be said of tabes dorsalis. 5. Lymphocytosis may occur in secondary and tertiary syphilis without clinical evidences of involvement of the nervous system. As a rule the cellular increase in such cases is far less than that observed in paresis and there is very little increase of albumin. 6. In arterio-sclerotic insanity a positive finding points to a syphilitic process, such as softened foci following specific arterial disease. 7. Epilepsy shows negative findings. 8. Alcoholism in all its varieties gives negative results—that is, when apart from syphilitic lesions. 9. A differential diagnosis is to be made between abscess of the brain and meningitis by the presence in the latter of increased cellular material. 10. It cannot be enough emphasised that the lymphocytosis is merely a symptom, and that only after consideration of all other symptoms of the disease should it be used to construe the case.

New Inventions.

AN ACHROMATIC ILLUMINATOR.

THE achromatic lens is often indispensable for examining the cornea, corneal surface, and iris, but the difficulty is that both hands are required to be employed in so doing, one in holding the lens and the other in supporting a focussing lens for condensing the light from a lamp. With the assistance of Mr. Davidson, optician, of 29, Great Portland-street, W., I have been enabled to overcome this difficulty by the introduction of an electric light attachment to the achromatic lens, by which one hand is left free to carry out the necessary manipulations of the lids while the examination is being conducted. The little appliance I have found a pleasure to use. The apparatus consists of an achromatic lens of about half an inch focus fixed in a metal clip, attached to which is the lamp-holder.



The current is controlled by means of a spring, by the pressure of which the light comes into use. The object of this arrangement is to prevent the waste of current when the lamp is not required. The lamp is of four volts and is screwed into the holder; it can therefore be easily replaced when either broken or fused. A dry battery is supplied which will probably last with intermittent use upwards of six months. The appliances can also be fitted with eight and 12-volt lamps for use with various accumulators and even with the ordinary house current by means of special adaptors which Mr. Davidson has designed and introduced. The whole appliance is contained in a small leather-covered box at a moderate cost.

PERCY DUNN, F.R.C.S. Eng.

THE LANCET.

LONDON: SATURDAY, JUNE 22, 1907.

The Royal Society of Medicine.

A MEETING of representatives of the various bodies taking part in the union of the London Medical Societies was held on June 14th, when the Royal Charter was adopted incorporating the 15 societies in question into the Royal Society of Medicine. Following this was the acceptance of a code of by-laws which had been prepared by the committee of representatives, and then the officers and the members of the council were elected. Although the labours of those who have during the past two years been engaged in devising an efficient scheme of amalgamation have not been crowned with complete success, yet they are heartily to be congratulated on having united no less than 8000 Fellows and members into a compact and influential body. A consideration of the history of previous attempts to form in London a corporate society of the medical sciences shows that the committee which undertook this endeavour had to face no light task. Sir WILLIAM S. CHURCH'S account of these attempts when the present scheme was first officially and publicly discussed in 1905 was full and interesting, and while referring our readers to his words[1] we will content ourselves with repeating that in the years 1808, 1850, 1860, 1867, and 1870 efforts were made to form an amalgamation based in every instance on an alliance between the Medical Society of London and the Royal Medical and Chirurgical Society, save in 1850 when the latter body was approached by the Pathological Society for a like purpose. The fruitless issue of all these attempts finds some reflection in the present qualified success, for the Medical Society of London and some other societies unfortunately have elected to remain distinct from the new scientific union. We feel it to be a matter of regret that the doyen of all the London societies has not seen its way to throw in its lot with its brethren, all of whom may be younger but some of whom are quite respectably ancient. However, the Royal Medical and Chirurgical Society having a full warrant to stand as representative for both of the two greater branches of the profession was able to form the foundation-stone of the new edifice, and the debt under which the medical profession is placed to this powerful body is a very great one, for the financial organisation of the new society rests to a great extent on that of its predominant partner. In emphasising this point we do not wish to cast any disparagement on the equally public-spirited action of the other constituent societies which we need not here enumerate; on the contrary, the self-denying ordinance by which they have forfeited their individuality *pro bono publico* must have the sincere commendation of all who have at heart the best interests of the advancement of medical science in England. It is gratifying to know that in the administration of the Royal Society of Medicine as much autonomy will be given to its constituent branches as is compatible with the compact and harmonious working of the whole body—this much is certainly due to the bodies which have undergone a voluntary absorption; although the actual labour involved in the administration of any branch will probably be less than when it had an independent existence, it would be regrettable if the officials responsible for its conduct were to lose that stimulus to a personal interest in its welfare that has been so prominent a feature of the societies as they existed before the amalgamation. It is just this personal touch, this active interest vivifying the many members of the body, that is essential to the due performance of the important functions that are for the mutual advantage of all, and which will prevent the work of so large an organisation from sinking into a level of official routine. Life is essential to progress and there must be a vital activity permeating the whole system if the best results are to spring from it, and these results will be attained by sectional officials, whilst sharing in the corporate interests of the whole society, maintaining their full zeal for the work of their own special branches.

Although, as we have said, the societies as such have made some sacrifice in forfeiting their independence, for their individual members the union should be an unqualified gain. It is not only that they will be admitted to participation in a wider sphere of professional interest for a considerably less total subscription than would have been demanded of them before had they belonged to several of the societies, but the saving in time to them will be a signal advantage amongst the many conveniences that will follow on the gathering of the various societies under one roof. The value of the libraries will increase by amalgamation, and the compactness of administration now possible will save an overlapping of interests in the different sections. But whilst each section will be concerned with its own business chiefly, the great advantage that will accrue to the members generally lies in the additional facilities which they will enjoy for following the proceedings of other branches both personally and by means of the Society's journal; it is above all things in the combination of interests of those branches of medicine that tend each year to become so specialised as to lose touch with medicine as a whole that we confidently predict will be found the chief justification for the institution of the latest of all the Royal Societies and the chief warrant for its success. *Floreat.*

Hospitals and Provident Dispensaries.

A CONFERENCE representative of the provident dispensaries of London was recently held at the residence of Mr. FRANCIS BUXTON, its object being the discussion of possible plans for closer coöperation between provident dispensaries, the hospitals, the medical profession, and the three great hospital funds. The dispensaries represented were Battersea, Blackfriars, Brompton, Chelsea, Deptford, East Dulwich, Greenwich, Hackney, Kennington, Kensal Town, Kilburn, Lewisham, Notting Hill, Paddington, St. John's Wood, Streatham, Tottenham, Wandsworth Common

---

[1] THE LANCET, April 15th, 1905, p. 1020.

Wandsworth Medical Aid, Westbourne Park, Western, West Ham, Whitechapel, Woolwich, and the Provident Department of the Metropolitan Hospital. Members of the council of the Metropolitan Provident Medical Association, of which Mr. Buxton is chairman, were also present. The following resolution was adopted on the motion of Sir William Bousfield, seconded by Mr. Harry J. Powell:—

> "That coöperation between all the provident dispensaries of London is desirable, whereby their aims and work may be advanced, reciprocal action between them and hospitals be promoted, and the transference of members from one dispensary to another be made more general."

A provisional committee, consisting of Sir William Bousfield, Mr. Francis Buxton, Sir Edward Brabrook, Mr. Carlton Lambert, Colonel Montefiore, Mr. H. J. Powell, and Dr. W. Winslow Hall, with a representative to be chosen by the Metropolitan Branch of the British Medical Association, was elected to carry out the objects of the resolution and to arrange for the appointment of a consultative council representative of all the provident dispensaries of London.

The provisional committee thus appointed will be engaged upon a work which has the sympathy of all who take interest in the welfare of the sick poor or who appreciate how far the various social and economical difficulties generally classed together under the head of hospital abuse are due to an absolute ignorance upon the part of the public of the proper place which the hospital, the dispensary, the infirmary, and the private surgery are designed to play in the relief of sickness, disease, and accident. There should be no better barrier between hospital out-patient departments and those for whom the services of these departments are not properly intended than the provident dispensary, and the more thoughtful of the medical men who have considered the problem presented by the glut of hospital out-patients regard the development of the dispensary system as the proper remedy for existing troubles. Medical men in the neighbourhoods where provident dispensaries exist know well enough how valuable they are and with what success they supply advice and treatment to just that class of person for whom the hospital out-patient department is not the proper place and who yet cannot be expected to pay ordinary medical fees. In the administration of the provident dispensary there is possible that local and individual discrimination without which charitable work can never be justly and effectively carried out. There is, moreover, in the vast majority of instances that desirable adaptation of means to an end which arises from the free intermingling of medical and lay opinion and endeavour. The field for provident dispensaries properly conducted is a very wide one. The public is taught by the services received at the dispensaries to regard the family practitioner as the first source of help. It is hard for the hospital authorities to prevent overcrowding, to weed out those who are not from those who are the proper recipients of advice and treatment for nothing in the case of illness not serious enough to demand admission to the hospital. The discrimination must come, so to speak, at the other end. The public must be taught that the out-patient department is the poor man's consulting-room, and the poor man's only. Those who are less poor must learn to visit a provident dispensary to which they subscribe or, better still, their own private medical man. Just where to draw the line between the three classes of individuals must always be a difficult matter and one permitting many errors. Almost any arrangement, however, must be better than the chaos which now exists, when the line is drawn nowhere and when the private practitioner sees his patients leaving him for an out-patient department at the doors of which they are deposited by their own horse and carriage. Such a case, though true, is of course an extreme. Yet such extremes are only possible when the existing system admits of very numerous minor flagrancies. Reciprocal action between hospitals and dispensaries, one of the objects aimed at by the provisional committee, may do much to prevent abuses of charity of this description. There is, as our readers are well aware, no problem more difficult of solution in connexion with medical charity than this question of abuse of out-patient departments. Nor, we feel sure, is there any miscarriage of charity which cries out more urgently for reform by reason of its prevalence. The harm which is done by the misuse of out-patient departments is not limited to the appropriation by the comparatively well-to-do of funds subscribed by charitable persons for the use of the extremely poor. It is not merely that the subscribers to hospitals are helping those for whom they did not intend their subscriptions but there is also to be considered the injury to the cause of medical science. What is the use, from the point of view of medical progress, of out-patient departments as they at present exist? What chance is there for genuine scientific work of any kind when physicians and surgeons are dealing with an overwhelming horde that has to be "seen" and treated somehow? The very idea of work of any kind, apart from the most rapid diagnosis, a little teaching, and the promptest treatment, is almost preposterous at the present time in connexion with the out-patient departments of London hospitals.

Several possible remedies suggest themselves for this deplorable condition of affairs. One, at any rate, worthy of all consideration and trial is to be found in thorough coöperation between provident dispensaries and the hospitals of their neighbourhood. For provident dispensaries to take the place, as there is no doubt they ought largely to do, of the out-patient departments of hospitals there may be necessary some increase in their number. In this direction it would be wise, we imagine, to move with extreme caution, for part of the very trouble to be treated arises from the existence of an excessive opportunity for gratuitous medical assistance. It would probably be found, however, that the chief fault in this respect lies not so much in superfluity but in lack of proper distribution. Some localities are undoubtedly over-supplied with medical charity, whilst there are others where the really poor find it hard to obtain the help that the philanthropic would wish to proffer them. Again, if provident dispensaries are to supply the amount of help which we think should be in their hands it will be necessary to standardise their methods to an extent which does not prevail at the present time. Some change of this kind would obviously be included in that part of the resolution which we give at the beginning of this article which refers to the transference of patients from one dispensary to another. In the matter of medical service there would, we anticipate, be no difficulty at all. The dispensary staffs could be enlarged at once, wherever it was thought necessary, by simple request. Medical men have never been found backward in giving their services to charitable institutions. Indeed, a little less generosity in this respect would but help in adjusting the scales. The terms of the resolution, in which it is desired that while the aims and work of the dispensaries may be promoted so also may reciprocal action between them and the hospitals, show that those who moved this resolution are fully alive to the importance of relieving hospital abuse. It could not be maintained for a moment, we think, that there is too little charitable effort in London with regard to the sick poor. Only it is to a large extent misdirected and badly administered. Obviously, then, if the amount of help is not to be increased, and we do not believe it needs increase, and at the same time one kind of help, that by provident dispensaries, is to be extended, retrenchment must be practised in another quarter. That quarter is, as we have sought to indicate, the out-patient departments of hospitals. One of the most recent general hospitals in Greater London, we allude to the Hampstead Hospital, will have an opportunity of leading the way in proper action with regard to this matter. Hampstead owns one or more dispensaries, and some, at any rate, of the local practitioners believe that there is no need for any out-patient department at all to the hospital. We offer no opinion on this particular case but mention Hampstead as one example of the many in which we hope to see beneficial results from the resolution which we quoted above. The *personnel* of the provisional committee gives us good hope that practical steps will be the outcome of its deliberations and an assurance that such steps will be to some extent in the much-needed direction of relieving hospital abuse in out-patient departments.

◆

Clifford v. Timms; Clifford v. Phillips; Hill v. Clifford.

HOWEVER irksome the law's delays may sometimes be to suitors four and a half months have sufficed to bring to a hearing the appeal against Mr. JUSTICE WARRINGTON'S judgment in the above cases and the result of the appeal has been that which was predicted tentatively in THE LANCET of Feb. 9th. In the circumstances we then confined ourselves to a brief statement of the principal points in his lordship's judgment which struck us as being most open to question, and if we felt confident that the judgment would be reversed we were content with hinting at an opinion which has now been justified. A more full statement of the interesting legal points involved will be found in another column (see p. 1732), but we may note serviceably here some of the main features. Certain partnership deeds entered into by one or the other of two brothers, R. E. CLIFFORD and ISIDORE CLIFFORD, with the three other parties to the litigation contained clauses which provided in similar, if not in identical, terms that "if either partner shall at any time during the continuance of the partnership be guilty of professional misconduct or of any act which is calculated to bring discredit upon or injure the other partner or the partnership business, the other partner shall be at liberty to give notice in writing of his intention to determine the partnership, and the partnership shall be dissolved and wound up under the provision of these presents in the same manner as if the offending partner had died on the day of such notice.' The CLIFFORDS were found guilty of "infamous or disgraceful conduct in a professional sense" by the General Medical Council in the usual way, and under the provisions of the Dentists Act, 1878, were struck off the Dentists Register. The question to be decided by Mr. Justice WARRINGTON arose out of the resolve of the brothers CLIFFORD to dispute the rights of their respective partners to terminate the partnership agreements on the ground that the General Medical Council had found the CLIFFORDS guilty of professional misconduct. Mr. Justice WARRINGTON, in a considered judgment, questioned the admissibility of the General Medical Council's order and of the report of the Dental Committee upon which that order was founded, and, further, drew an ingenious and not wholly comprehensible distinction between "professional misconduct" (the term used by Mr. TIMMS in giving notice to terminate the partnership in his case) and the "infamous or disgraceful conduct in a professional sense," which formed the ground of the removal of the CLIFFORDS from the Dental Register. The Court of Appeal, in dealing with these points, delivered long and exhaustive judgments, but for our present purpose it is sufficient to refer to the words quoted elsewhere of the Master of the Rolls, who held that the order of the General Medical Council was evidence, as a "judgment *in rem*." His lordship further thought that "it was idle for a man who in the language of section 13 of the Act of 1878 has been guilty of 'disgraceful conduct in a professional respect' to contend that he has not been guilty of 'professional misconduct.'"

With these conclusions it would be difficult not to agree, and they dispose of a judgment which, had it been upheld, would have caused a precedent to be established of an extremely inconvenient character and one which put an artificial misconstruction upon more or less plain words used in a matter appertaining to their own profession by men who were not lawyers, with a clear intention to provide against contingencies familiar to them. As it is, in spite of passages in the judgment of the Master of the Rolls which seem to justify the view that removal of the name of one of two medical partners from the register would, *ipso facto*, terminate the partnership, we suggest, as we did in our leading article of Feb. 9th, that any clause in a partnership such as we have quoted above should contain special reference to the possible action of the General Medical Council, as well as such other general descriptions of acts injurious to the partnership business as may be thought desirable. We suggest, in short, that it should be expressly agreed in all cases that the fact of a partner's name ceasing to be upon the Medical or Dental Register should put an end to his partnership *ipso facto* and without any notice being given to him as provided in the cases of the CLIFFORDS.

It is of some interest to note that a peculiar feature in the partnerships which gave rise to the appeal upon which we have commented, or in one of them, was introduced by a proviso that on the death of the partner of the named Clifford his brother was to step into his shoes. Therefore, as the dissolution through unprofessional conduct was to have the same effect as the death of the offending partner, it would also introduce his brother in his place. Clauses capable of producing such possibly inconvenient results require consideration before the deed containing them is signed. Other features peculiar to the cases of the Cliffords, such as the fact that Mr. Phillips, a party in one of them, had entered into partnership with one of the Cliffords without being himself on the Dentists Register, were dealt with in the judgments delivered in the Court of Appeal, but do not affect the question, which was certainly one of interest to the medical and dental professions at large, whether a professional man might be saddled against his will with a partner unable to carry on the business of the partnership, in spite of a clause in the partnership deed obviously drawn with no other intention than to prevent such an occurrence.

Annotations.

"Ne quid nimis."

AN ACT TO MAKE THINGS WHAT THEY SEEM.

Surely the time has come when room should be found in our legislative machinery for an Act which shall be applied to articles other than foods and drugs yet which could be administered in much the same way as is the Sale of Food and Drugs Act. It is brought home to us almost every day that the public is imposed upon not merely in regard to articles of food and drink but in regard also to articles of clothing and other materials. The local authorities, we suggest, should be possessed with powers to apply in a practical manner the provisions of the Merchandise Marks Act or a similar measure. The public is not very adequately protected against such substitutions as cardboard being sold as leather, cotton as wool or silk or flannel, celluloid or bone as ivory, and a host of other things which are not what they seem. The evidence of chemical analysis is hardly wanted in such cases and a staff of analytical chemists would not be indispensable for the administration of such an Act, though it must be admitted that experts, or at least a body of intelligent men, would have to be appointed who could discriminate at a glance the genuine from the false in such cases as are quoted above. We know that there are such men and the various trades concerned know it also and competent inspectors could be drawn from their ranks. The subject is not outside our province, for many such substitutions as we have mentioned are intimately associated with questions of health. The boot, for example, which is not made of leather but is what might aptly be described as a cardboard sandwich—that is to say, contains slices of cardboard inserted in the sole—does not secure that protection against weather which the wearer expects from it. He is not only deceived but his health may be unfavourably affected by wearing boots which fail to guard him from the effects of wet and cold because they are not made entirely of the weather-proof material which good leather is. He might as well look for relief in a belladonna plaster which contains no belladonna. In that case, however, he is protected, or at least means of protection are provided in the shape of the Sale of Food and Drugs Act. Again, health might easily be injured by the wearing of a material loaded with mineral substances, amongst them being, in all likelihood some of a distinctly poisonous or irritating nature. A person is protected against the possibility of poisons getting into, or being used in, his food so far as human efforts can go. For here once more the Sale of Food and Drugs Act exists to operate in the interest of his health and well-being. Then is it unreasonable to demand that he should be protected equally in regard to other things which are essential to his comfort and well-being?

THE CONFLICT OF HEREDITY AND ENVIRONMENT.

A thoughtful paper on the subject of Heredity and Environment Relative to Man was read before the May Chapter of the Guild of St. Luke by Surgeon-Colonel F. H. Welch, F.R.C.S. Eng., in which he traversed a considerable range of ground of an enormous speculative territory, concluding with a brief diversion into the thorny paths of the freewill controversy. His object was to show the vast importance of his subject in its bearing on the general status and the progressive development or retrogression of the individual and the race, and to study the manner in which we may best apply its lessons to the sphere of practical politics. In considering the influence of heredity on the organism he echoes a slight protest against the modern scientific consensus of opinion that so strongly supports the non-inheritance of acquired characteristics, although he carefully avoids dogmatism on either side, a state of mind to which the present condition of physical science may well incline the seeker after truth. He does not consider that in the present state of educational development there are sufficient individual altruism and national conscience to make practicable the proposal to regulate our social ills by a system of compulsory "Eugenics," and, indeed, he repeats the uncomfortable observation that, considering heredity alone, our increased care for the lives of the children of the less favoured classes seems to clash with the method of evolution by natural selection, whilst no artificial selection is yet available to replace it. But a more hopeful note is sounded when he turns to consider environment, and in this he sees the weapon of salvation for the race that evolution of intellect has given us, but he deprecates the national reluctance to wield it vigorously against the dragon of degenerative tendencies. In pointing out the enormous control that environment can have over hereditary tendencies, he instances the astonishing work of Robert Owen for 26 years in New Lanark. That philanthropist at the beginning of the last century grasped this principle of improvement and thereby redeemed from utter social degradation a community of 2500 persons, without recourse in any case to legal punishment; like excellent results of attention to environment may be seen in the Barnardo homes to-day, and the educated portion of the community may well put to itself Surgeon-Colonel Welch's trenchant questions on the side of environment, as to what means commensurate to the needs are in operation to curtail the deteriorating influence of town life with its overcrowding on the physique and stamina of our urban population; to give through a sufficiency of decent room-accommodation the chance of the growth of modesty and continence among the young of both sexes; to abolish the superadded temptations to incontinence through the facilities from open solicitation in the streets; to provide institutes and wholesome recreation for men and boys and girls as counterpoise to the poor home, the beershop, and the vicious teachings of the streets; to train up our rising youth and adults to a sense of patriotism and of what duty demands towards preparing themselves to defend their country and homes against outside aggressors; and to foster the religious sentiment by agencies and ways sufficient in amount and right in character. We are in accordance with the author of these words in his contention that it is the paramount duty of the race to search out by all means and to apply in every way the right methods of improving the environment of its units, for if we are to sit down impotently under the incubus of heredity and submit as did the doomed Greek family to its Ate, then, indeed, must we consider the purpose of existence to be in vain. It is in the control of heredity by self-planned environment that the true freedom of man will surely stand manifest.

WEIGERT'S LIFE AND WORK.

AN interesting biographical sketch of the life and work of Carl Weigert has recently been published in Germany by Professor Robert Rieder[1] of Bonn. The great contributions made by Weigert to pathological anatomy and histology, to general pathology, bacteriology, neurology, and to the technique of microscopical methods are considered in detail, while the influence which he exerted upon the medical sciences is carefully outlined. Professor Rieder shows a genuine affection and a profound admiration for the subject of his sketch and presents in comparatively few but well-chosen words an attractive picture of the personality of Weigert whose single-minded devotion to science, untiring persistence in perfecting the methods which he introduced, and striking originality combined to render him one of the greatest investigators of his time. These brilliant gifts were associated with a nature of almost childlike simplicity but at once so pleasing and loveable that Weigert possessed countless friends and admirers. Weigert was born in Silesia in 1845 of Jewish parentage and after his student career was completed acted as assistant to Waldeyer in Breslau from 1868 to 1870, leaving to serve as an army surgeon in the Franco-Prussian war. On his return to civil life he was assistant to Lebert from 1871 to 1873, becoming assistant to Cohnheim in Breslau in the following year. In 1878 he went with Cohnheim to Leipzig and became extraordinary professor of pathological anatomy. After the death of Cohnheim in 1884 Weigert resigned this post and spent the rest of his life at the Senckenburg Institute at Frankfort-on-the-Main, of which he was director. Professor Rieder is righteously indignant that Weigert never received a "call" to the professorship at any of the great universities and asks if pathological anatomists of his calibre were so plentiful in Germany that there was no room for him; but we may agree with Professor Rieder that science was the gainer by this, for Weigert's great energies were free to be devoted to research and to the instruction of those who visited his laboratory, comprising representatives from almost every civilised nation. His work was so peculiarly his own, so truly scientific, that it may be doubted whether, even in his own country, the great significance and value of his work are even yet fully recognised, for his papers were mostly published in scientific journals or transactions, were often highly technical, and were the outcome in many cases of years of persistent labour. His method for staining the white substance of the nerve fibres represented three years' diligent work, while he studied his neuroglia method for 17 years before he published his results, in spite of the earnest advice of well-meaning friends that he should record some of his observations. This singular pertinacity and whole-hearted devotion appear to have been strikingly characteristic of the man. His fame might, perhaps, have been more public if he had published a text-book, but as he was wont half jestingly to say, "They are too full of other people's wisdom." Weigert was essentially an investigator, as a study of the list of 97 papers published by him shows. His work was too comprehensive in its scope to admit of more than passing reference here, but it may be remembered that, in addition to his extensive researches on histological subjects, he was the first to apply differential staining methods to bacteria and to stain them in sections of hardened tissues, while Koch has borne testimony to the assistance afforded to him in his researches by Weigert's discoveries. Among other pathological studies we may also refer to those on the eruption of small-pox, the exudate of diphtheria, the process of coagulation necrosis, the phenomena of inflammation, and the primary tissue degenerations. Appended to this biographical sketch are two short appreciations, one by Professor Edinger on Weigert's services to neurology, in which the state of histological research in regard to the nervous system before the introduction of the methods of Weigert is described, and another by Professor Paul Ehrlich on Weigert's contributions to histological science, which concludes with the striking tribute, "He has yielded us not only methods but a system." Professor Rieder's book affords an interesting character sketch of a great personality as well as a valuable summary of his contributions to science and the book should be read with great profit by all who are interested in the advances made in medical science in the nineteenth century.

THE ANTIGONE AT BRADFIELD COLLEGE.

DURING the last two weeks the triennial Greek play has been performed in the beautiful model theatre built 17 years ago in the chalk-pit at Bradfield College. It hardly falls within the function of a medical journal to offer a detailed criticism on either the acting or the significance of the Antigone although the clashing of interests of the individual and the State is not without parallel in the experiences of modern medicine. From a medical point of view the acting of Mr F. R. Barry as Teiresias was conspicuous, as he really did convey the effect of being blind as well as of being a very disagreeable old gentleman, whilst Haemon made a most realistic "corpse," far more so than that of the ill-starred queen. The acting of Mr. C. R. Eddison as Antigone, Mr. A. G. R. Garrod in the exacting part of Creon, and Mr. G. R. Hamilton as First Messenger was extraordinarily good and their enunciation would have done credit to a London stage. Creon shone most in his spirited quarrel scenes, and Antigone found a representative who gave full value to the dignity and sweetness of a character only matched by our Shakespeare's heroines. The choric dancing and chanting were always interesting, and the orchestra with ancient "flutes" and lyres contributed much to the success of the play. The talent displayed by the Warden in taking the part of the Coryphaeus at a day's notice was very noteworthy, his statuesque poses giving a truly Greek stamp to a dramatically effective rendering of the part. An English verse translation of the play by the sixth form contained many strong passages. The arrangements for the transport and refreshment of the guests were as perfectly organised as they could be and enhanced the enjoyment of a memorable production.

BRASS-FOUNDERS' AGUE.

THE inhalation of fumes arising during the casting of brass was known many years ago to produce a disease called brass-founders' ague. The question was debated for a long time as to whether the injurious agent was copper or zinc, but it appears to be concluded now that zinc is the chief factor. Moreover, zinc oxide is much more readily volatilised than is copper oxide. The symptoms are described as tightness and oppression of the chest with indefinite nervous sensations followed by shivering and profuse sweating. The

[1] Carl Weigert und seine Bedeutung für die Medizinische Wissenschaft unserer Zeit. Eine biographische Skizze von Dr. Robert Rieder. Berlin. Julius Springer. 1906. Pp. 141. Price 3 marks. (Carl Weigert and his Influence on the Medical Science of Our Times, a Biographical Sketch by Dr. Robert Rieder.)

Home Office has recently issued a circular in which it is pointed out that certain regulations should be observed in connexion with brass-founding. Thus it is proposed that the pouring of brass should be prohibited unless there be (*a*) an efficient exhaust draught for the removal of the fumes at, or as near as possible to, the point of origin, and (*b*) efficient arrangements to prevent the fumes from entering any room or factory in which work is carried on, and (*c*) free openings to the outside air in the upper part of the room. Provisions are also laid down for the maintenance of a lavatory supplied with warm water, soap, nail brushes, and so forth. Females are not allowed to work in any process whatever in which the pouring of brass is carried on. The regulations have been prepared after careful inquiries, extending over a period of several years, into the condition of the industry and the working of special rules, with the result that it has been shown that these rules do not adequately provide for the protection of the workers and that further precautions are necessary. As will be seen, the most important proposal in the regulations is the requirement of efficient means to remove the fumes which are the chief source of injury to the health of those engaged in the casting shops. A system of exhaust ventilation is therefore indicated and demanded. The regulations just issued are subject to further consideration and objections may be lodged by occupiers or the workpeople themselves with the Secretary of State within 40 days from the date of the circular, which is June 14th.

"INFANT CONSULTATIONS" AT THE ST. MARYLEBONE GENERAL DISPENSARY.

WE have received the report of the first year's working of the new scheme for preserving infant life which is on trial at the St. Marylebone General Dispensary. During the 12 months which are covered by this report 98 babies were taken to the "consultations" and of this number 58 attended regularly, 21 irregularly, and 19 were taken only once for examination. The progress of the babies who attended regularly is stated in the report to have been highly satisfactory in 16 cases, satisfactory in 30, and unsatisfactory in 12. Only two deaths have been recorded during the year, a result which may be considered extremely good in view of the fact that the greater proportion of the infants sent to the "consultations" were the difficult or intractable cases met with by the health visitors of the St. Marylebone Health Society in the course of its work. The report further states that "up to the present the experience gained at the 'consultations' shows that with careful instruction and subsequent supervision there is no pressing necessity to provide free allowances of sterilised milk or of milk otherwise prepared. It is found that other than breast-fed cases do excellently when the mothers are left to obtain the milk through the ordinary commercial channels." From an educational standpoint and on sociological and economic grounds this may be considered an improvement on methods which depend on the principle of free distribution, for such methods offer a premium on bottle-feeding and tend to diminish the parental sense of responsibility. We are asked to give notice that a public meeting will be held in connexion with the above scheme on July 2nd at the Portman Rooms, Baker-street, W., at 4 o'clock. At this meeting the chair will be taken by Lord Robert Cecil who is promoting a Bill in Parliament for the Early Notification of Births and who takes a great interest in all measures which aim at checking infant mortality. The prizes which have been offered by various individuals interested in the scheme will be distributed by the Duchess of Sutherland among the mothers who have successfully carried out the instructions given at the "consultations." Addresses will be delivered by Lord Robert Cecil, by the Duchess of Sutherland, and by others interested in the work of the dispensary and of the Health Society. The infants who have secured prizes or certificates will be on view in a separate room. Admission to the meeting is by invitation, or by tickets, 10*s*., 5*s*., and 2*s*. 6*d*., which can be obtained by application to the secretary of the Dispensary, 77, Welbeck-street, W. The proceeds resulting from the sale of tickets are to be devoted to the furtherance of the scheme.

STENOSIS OF THE TRACHEA DUE TO HYPERTROPHY OF THE THYMUS.

CASES of sudden death with symptoms of asphyxia in infants associated with hypertrophy of the thymus have long been recognised. But considerable doubt exists as to their pathology. According to some the enlarged thymus acts mechanically either by direct pressure on the air passages, by interference with the vagus nerves, or by exciting reflexly spasm of the glottis. According to others the enlarged thymus is merely an index of a general lymphatic dyscrasia which entails feebleness. However, there seems to be no doubt that in some of the cases there was distinct pressure on the air passages. In the *Journal of the American Medical Association* of May 25th Dr. C. Jackson has recorded a case in which such pressure certainly existed and which derives additional interest from the fact that it is the only case in which the existence of the pressure has been demonstrated during life. A boy, aged four years, was admitted into hospital on August 30th, 1906. He had always been well until six weeks before, when he awoke at night with an attack of "croup." Since that time he suffered from increasing dyspnœa. On examination there was considerable expiratory dyspnœa which was worse when he sat erect. The colour and general appearance were good and there were no signs of the "lymphatic constitution." Over the sternum there were a tympanitic note, increased vocal resonance, tracheal breathing, and a whistling tracheal rhonchus. Dr. Jackson was asked to examine the case and finding the larynx free from obstruction suspected that there was a foreign body in the trachea and ordered a radiograph to be taken. This showed the shadow of an enlarged thymus gland. On Sept. 5th he opened the trachea under infiltration anæsthesia. The rings seemed of normal resiliency and the thymus was seen to extend abnormally high in the neck, reaching to the thyroid and rising when the patient coughed. On passing a bronchoscope he discovered a scabbard-shaped trachea extending from the second to the fourth ribs with a chink of not over two millimetres on inspiration and one millimetre on expiration. The passage of the bronchoscope instantly relieved the dyspnœa. When the bronchoscope was withdrawn no air entered and asphyxia was threatened. A long cannula was therefore inserted, giving partial relief. From measurements taken a very long tracheotomy cannula extending to within one centimetre of the bifurcation of the trachea was made. It gave complete relief and was worn for four weeks. On the following day there was profuse discharge from the tracheotomy wound and numerous large moist râles were heard all over the lungs; they diminished in a few days. On Oct. 2nd a second operation was performed. On removing the cannula the trachea completely collapsed. The tracheoscope showed mild tracheitis. The cannula was re-inserted. A curved transverse incision was made below the upper border of the sternum to avoid the tracheal wound and carried down to the thymus gland, the sternal attachments of both sterno-mastoids being divided. When the child coughed the thymus bulged into the wound. The finger was passed down into the mediastinum. Numerous fine adhesions to the sternum were broken down. The thymus was drawn up with forceps until its tip projected from the wound. Several fibrous attachments were ligatured and the thymus was removed. The sterno-mastoid tendons and the wound in the skin were sutured. The child stood the operation very well. The tracheal cannula was removed on the eighth day after operation. There was never the slightest stridor after the thymectomy and no ill-effect seemed to have been produced on the blood or nutrition. Microscopic examination of the thymus showed only simple hypertrophy. This is the seventh case on record of cure by thymectomy of "thymic asthma," or, more correctly, thymic tracheo-stenosis. In performing tracheotomy for its relief a long cannula, which will reach below the obstruction, is necessary. The want of this seems to have been the cause of death in some of the cases.

A DANGEROUS DRY HAIRWASH.

HAIRDRESSERS seem to be at their wits' end to devise an effectual yet safe dry wash for the hair. The chief object of such a wash is, of course, to remove grease and therefore dirt, but unfortunately the best solvents for grease are as a rule volatile and inflammable. Light petroleum spirit appeared at first to be excellent for the purpose until some serious accidents occurred in which somehow or other the spirit was ignited with results disastrous to the hair in some cases and in others to the person also. We have had occasion before to refer to the dangers of employing exceedingly inflammable and volatile liquids such as benzene and petrol as dry hairwashes. If they are used at all the cleansing process should be conducted without risking the slightest chance of the vapour catching fire—in a place, in short, where there is no flame. Even the electric light does not confer immunity from an accident, since any small sparking that may happen at the points of contact at the switch or the lamp is sufficient to start an explosion of air and inflammable vapour. Convinced apparently of the dangers attending the use of liquids which give off inflammable vapours, some of the hairdressing trade have evidently been induced to give them up in favour of a less volatile and practically non-inflammable yet grease-extracting liquid—namely, carbon tetrachloride. It is not surprising to find that the barber is absolutely ignorant of the nature and properties of this chemical substance, and most people would ask, "What is it?" Used largely as a solvent for grease, wax, and rubber in certain technical trades, carbon tetrachloride so far is little known to the ordinary person and certainly less known than is chloroform, to which it is intimately related. As a matter of fact, carbon tetrachloride is just as much an anæsthetic as is chloroform. It is not quite so powerful perhaps, because it is less volatile and its boiling point is higher. But that it may produce anæsthesia sufficiently to develop alarming results is evident from the case which we record this week. This fluid was being used after the manner of an ordinary dry hairwash. Almost at the moment of its application the customer, a lady, cried out that it was far too strong, but the operator replied that it would soon pass off. In the words of our contributor, "her next recollection was that of finding herself propped up on the floor, a wet towel round her head, the window wide open, and a very frightened hairdresser fanning her vigorously with a towel. She was informed that she had been unconscious for five minutes and had been a very nasty colour." She said that she felt just as though she had been taking chloroform and suffered from sickness for some time afterwards. We should have thought that the judicious use of soap and ammonia water followed by rinsing with weak spirit would serve as an effectual wash for the head with long hair which would afterwards dry reasonably quickly. Ladies, however, evidently regard this method as much too slow compared with the rapidly drying but highly inflammable petroleum, and so they run serious risks rather than exhibit a little patience. In passing, it is interesting to observe that most of, if not all, the fluids the vapour of which produces anæsthesia when inhaled are solvents of fat. Ether, chloroform, ethyl chloride, benzene, and light petroleum serve as instances, and apart from the intense inflammability of some of them they should never be countenanced as safe agents in the hands of the hairdresser.

THE CARE OF TUBERCULOUS CHILDREN.

THE needs of tuberculous children have been sadly neglected in this country. Some doubt seems to be arising as to whether open-air treatment for the adult, although offering the best means for dealing with tuberculosis in the working man and woman, is that specific which early enthusiasts proclaimed it to be. We are beginning to understand that medically, as well as economically, it is wisest to begin at the beginning. Greater attention must be devoted to the protection of tuberculously disposed children. The committee of the Children's Home and Orphanage, the headquarters of which are at Bonner-road, London, N.E., with branches throughout the country and in Canada, and caring for nearly 1800 children, finds that something like 25 per cent. of its little folk are predisposed by heredity to tuberculosis. It has, therefore, determined to establish a sanatorium in a suitable country district near London for these cases. Dr. T. N. Kelynack, the editor of the *British Journal of Tuberculosis*, has accepted the invitation to act as honorary physician and medical adviser, and full particulars may be obtained from the principal, Dr. A. E. Gregory, at the London Branch Children's Home and Orphanage, Bonner-road, N.E. We are informed that the forthcoming issue of the *British Journal of Tuberculosis* will contain articles by British, American, and German experts on the tuberculosis problem as it affects infancy and childhood.

MSS. OF JOHN HUNTER'S LECTURES.

IT has been suggested to us that the title of an annotation in a recent number of THE LANCET ("Original Notes of John Hunter's Lectures") might convey the impression that a unique discovery had been made. This is not the case of course. The manuscript, which has just been presented to the Royal College of Surgeons of England by a medical man of long standing, who thus generously commemorates his jubilee as a Member, has long been known in the College library in the form of one of those exquisitely written transcripts for which Clift, the conservator, was justly noted in his day. This transcript was made by William Clift in 1835, and on returning the original to Dr. T. J. Walker's predecessor in his Peterborough practice he apologises in an extant letter for having kept the book for eight long years. Clift was a leisurely and faithful transcriber of all that concerned his great master John Hunter and his transcripts were often made at rather late hours. More than one ends with some such note as "finished this copy at 2 A.M.," usually in mid-winter. There are a number of volumes of notes of John Hunter's lectures on surgery in the library of the Royal College of Surgeons of England. The best known is the quarto four-volume MS., dating from 1786, which was reprinted by Palmer in his classical edition of John Hunter's works. More recently Sir John Tweedy has presented a fine MS., containing a note by Clift to the following effect: "Mr. Eyles's copy of Dr. Joseph Adams's account of Mr. Hunter's lectures on the Principles of Surgery. No date. Lent to me June 4th, 1827, to compare with Mr. Twigge's and Mr. Pearce's copy." Another MS. of "Lectures on the Principles of Surgery," in an unknown hand, was bought at a sale at Sotheby's in May, 1904, where it was "knocked down," with other interesting MSS. in a bundle, for 1s.! Scientific and medical men were evidently absent from this sale. We are reminded in this connexion of Mr. Blades's story of finding a black-letter Caxton, which in the auction-room would have fetched many hundreds of pounds, in a region that cannot be named in polite society. The people of the farmhouse where he was staying had been steadily working through several volumes of these priceless incunabula. On the corner of the mill-board cover of the Hunter MS. last discussed are the words "Jno. Hunter," but it is impossible to say who wrote them.

EPIDEMIC CEREBRO-SPINAL FEVER.

IN London during the month of May there were 21 cases notified as cerebro-spinal fever, five of them belonging to Lambeth and two each to St. Pancras, Poplar, Bermondsey, Battersea, and Deptford. During the same period seven deaths from the disease were recorded—namely, four in Lambeth and one each in Fulham, Bermondsey, and Deptford. In Scotland during the week ended June 15th there were 14 deaths from this cause registered in Glasgow, seven in Edinburgh, and two in Leith. In Glasgow the weekly report issued on June 14th showed that there were at that time 98 cases under treatment. In Belfast during the week ended June 15th there were 15 deaths registered as being due to this cause.

THE DIAGNOSIS OF DILATATION OF THE DUODENUM.

RECENTLY attention has been drawn to dilatation of the duodenum by the observation of surgeons during operations. Ochsner has pointed out the existence of a duodenal sphincter and many writers have shown that dilatation may result from obstruction due to traction of the root of the mesentery over the lower end of the duodenum in conditions of enteroptosis. In the *Boston Medical and Surgical Journal* of May 9th, Dr. A. Christian has reported the following case. A man, aged 70 years, was admitted into hospital on Dec. 31st, 1903, complaining of pain in the stomach after eating, occasional vomiting, and constipation. The abdomen was flaccid and not tender. Pressure on the epigastrium and left hypochondrium caused eructations of gas. Under gastric lavage and cathartics improvement took place. In one month ten pounds were gained in weight. Before the patient's discharge on Feb. 1st, 1904, inflation showed that the lower border of the stomach was three cubic centimetres below the umbilicus. The patient remained well until June, when the symptoms recurred. He improved again but was readmitted in March, 1905. An attempt to inflate his stomach by means of a seidlitz powder was unsuccessful. A stomach tube was passed and 115 ounces of water were put in. Of this only 48 ounces could be recovered. On a subsequent occasion with the patient sitting up the lower border of gastric resonance was found to be 13 centimetres below the costal margin in the left mamillary line and two centimetres below the umbilicus and to reach the right costal margin at a point six centimetres to the right of the median line. Further to the right there was an area of tympany, the lower border of which could not be well defined. By means of the stomach tube 93 ounces of water were introduced and the lower border of the tympany was raised two centimetres on the left, and the area of tympany on the right disappeared. Only 67 ounces of water could be recovered. The lower border of tympany was now 17 centimetres below the costal margin on the left and six centimetres below the xiphoid. Inflation with air lowered the line of tympany four and a half centimetres. A tentative diagnosis of hour-glass stomach or dilated stomach and duodenum was made. On April 21st, 1905, gastro-enterostomy was performed. The stomach was found enormously dilated but there was no pyloric obstruction. The patient stood the operation badly and died in the evening. The necropsy showed dilatation of the stomach and duodenum. The latter was 12 centimetres in circumference. There were also chronic adhesive pericarditis, hypertrophy, and dilatation of the heart, and chronic nephritis. This case shows the possibility of determining by the use of the stomach pump tube the existence of two pouches so connected by a patulous opening that both can be filled with water which can be syphoned back from only one. Such a condition would occur both in hour-glass stomach and in duodenal dilatation with pyloric relaxation. In the latter condition the second pouch would be well to the right side, as in the case described above

HAIRS AND BRISTLES AND ANTHRAX.

THE Secretary of State for the Home Department issued a circular letter in May last year which inclosed a copy of a report on the incidence of anthrax in the manipulation of horsehair and bristles. The proposals contained in the circular have since received the consideration of a number of manufacturers and others interested in the industry. It is now suggested that all horsehair from China, Siberia, or Russia (with the exception of white or light-grey hair which might suffer damage in the process) should be disinfected before undergoing any process other than those of opening or sorting. It is recommended that arrangements should be made, at least as regards a large proportion of the material, for its disinfection by, or on behalf of, the importers before distribution to the manufacturers. If this procedure were adopted it would diminish the regulations applying to the factory or workshop. In view of the small proportion of cases that can be traced to the use of bristles it has been decided tentatively to exclude bristles from the scope of the regulations, but the hope is expressed that the installation of disinfecting apparatus may lead manufacturers to adopt the practice of the disinfection of the undressed bristles known in the trade as "riflings" and so to render the manipulation of such material free from risk. That regulations in this trade are desirable is emphasised by the fact that between Jan. 1st, 1906, and March 31st, 1907—the period since the figures referred to in the report were made up—17 cases of anthrax, including six deaths, occurred in connexion with horsehair and bristles. The regulations proposed are to receive further consideration and any communication in regard to them is to be sent in to the Home Office not later than July 7th.

THE MILK QUESTION IN NEW YORK.

AT a meeting of the Medical Association of the Greater City of New York an instructive debate on the various questions of milk-supply has recently taken place in New York. An interesting part of this debate related to municipal and State regulations, in which connexion an admirable paper was presented by Dr. W. Goler, health officer of Rochester, New York, who is a recognised authority on the subject. He said that however practical in their labours the men engaged in the storing and distribution of milk might be they could not be scientifically trained either in the housing and feeding of cattle or in handling and transporting milk. To insure a safe milk-supply to a city Dr. Goler considered that a sufficient number of inspectors was necessary to inspect really and not merely to report. They should collect monthly samples for bacteriological and chemical examination from the farms, and at least a sample from each shop offering milk for sale should be similarly examined every three months. There should be a daily inspection of the incoming milk at each railroad station for (1) condition of and housing of cans and bottles in shipment; (2) condition of pty cans reshipped; (3) temperature of milk; and (4) spection of railroad samples to guard the retailers against and on the part of the wholesale dealers. "And the untry part of the work," remarked the speaker, "is even greater importance than the city part. The rritory from which a city draws its milk-supply must be apped out, the situation of the dairies ascertained, the roads amined, the railroad facilities noted, and the routes laid ut, so that every farm which sent milk to the city may be bjected to systematic inspection every month." Dr. E. B. orhees of New Brunswick, New Jersey, a director of he New Jersey Agricultural Experiment Stations, dealing ith the same question of systematic State control, ointed out that the State should also make such regu-ations for the retailer as should guarantee proper are in transporting and storing of the milk and its istribution as well as the requisite cleansing and return f the vessels in which the milk had been trans-orted. In the articles upon the railway transport of milk o London recently published in The Lancet stress was aid upon the absence of proper facilities for bringing milk o London by rail in a speedy and cleanly manner. The ubject is an enormously important one and seems to be iscussed more seriously and to be tackled more ener-getically in America than in England, though the enormous istances to be traversed by American trains should make organisation more difficult.

THE TEACHING OF HYGIENE AND TEMPERANCE IN SCHOOLS.

The question of imparting systematic instruction in the principles of hygiene and temperance to school children has during the past year been occupying the careful attention of many prominent members of the medical profession and others interested in the health of the nation. We published in November last an account of the proceedings of the deputation to Mr. Birrell advocating the teaching of hygiene and temperance in elementary schools, and urging that not only should these subjects be specifically introduced into the curriculum of the code but that facilities for special training in them should be afforded to school teachers and that they should be reported on by His Majesty's inspectors. The deputation met with a courteous and sympathetic response in which Mr. Birrell suggested that the introduction of these subjects into the science curriculum should be gradually accomplished and that the training of the teachers was the most important step to be taken. The public interest thus aroused in the matter has recently found expression in a petition to Mr. McKenna, signed by nearly 200 Members of Parliament, supporting similar objects. As we reported in our last issue, Lord Strathcona headed a deputation to the President of the Board of Education on June 6th again urging this matter on his attention and suggesting the establishment of a medical bureau in the Education Department, to which Mr. McKenna replied that until the Bill which contained provisions dealing with the medical inspection of school children had become law he could not declare the settled policy of the Board of Education on the subject. A strong local reflection of the central interest that has been taken in this matter is shown in the report for 1906 made by Dr. Alfred Greenwood to the education committee of Blackburn, of which he is the medical officer. During the year evening classes on school hygiene were given to school teachers, based on a syllabus that is printed in the report, which summarises a course of 25 lectures and to which the attention of other local educational authorities may be given with advantage. As a result of the Blackburn lectures eight school teachers from that town passed in one or both parts of the examination in hygiene in its bearing on school life conducted by the Royal Sanitary Institution, and the committee has decided to ask all future applicants for teachers' posts whether they have any similar qualification in school hygiene. Dr. Greenwood states in his report that the importance of teaching hygiene is not yet appreciated sufficiently and we trust that the vigorous attempt to grapple with it made in Blackburn will stir up other towns to follow its example.

The medals and prizes gained by the successful students at Guy's Hospital will be distributed by Sir A. W. Rücker, F.R.S., the Principal of the University of London, on July 4th, when a garden party will be held at 3.15 P.M. Academic costume will be worn on the occasion. The laboratories, museums, college, the Henriette Raphael Nurses' Home, and the wards will be open to inspection from 3 to 5.30 P.M.

The medical officer of health of the Cape Colony reports that during the week ending May 18th no case of plague in man was discovered, but two cases discovered during the preceding week remained under treatment. On May 24th a case of plague was discovered in a European female who was removed to the local plague hospital, so during the week ending May 25th three cases were under treatment.

The Local Government Board has established new premises for the preparation and distribution of glycerinated calf lymph for the use of public vaccinators and has notified that all applications for calf lymph should now be addressed to the Government Lymph Establishment, Colindale Avenue, The Hyde, N.W.

The first general meeting of the medical and surgical sections of the Royal Society of Medicine will be held at 20, Hanover-square, London, W., on Monday, June 24th, at 5.30 P.M., for the purpose of electing officers and council and transacting other necessary business.

The death is announced of Dr. Julius Dreschfeld, consulting physician to the Manchester Royal Infirmary, and for many years professor of medicine at the Owens College. We hope to publish an extended notice of his career in a future issue.

Dr. R. Welsh Branthwaite, His Majesty's inspector under the Inebriates Act, will deliver the second Norman Kerr memorial lecture, under the auspices of the Society for the Study of Inebriety, on the evening of Tuesday, Oct. 8th.

The first meeting of the Society of Tropical Medicine and Hygiene will be held at 20, Hanover-square, London, W., on Wednesday, June 26th, at 8.30 P.M. An address will be delivered by the President, Sir Patrick Manson.

Mr. H. Rider Haggard, J.P., will distribute the prizes to the successful students at St. Thomas's Hospital in the Governors' Hall on Wednesday, June 26th, at 3 P.M.

The annual meeting of the general committee of the Imperial Cancer Research Fund will be held at Marlborough House on Monday, July 1st.

Water-Supply of Paignton.—A Local Government Board inquiry was recently held at Paignton, Devonshire, into the application of the Paignton urban district council to borrow £12,861 for the distribution of the new water-supply in the town. This is in addition to the £111,000 for which borrowing powers have already been obtained.

METROPOLITAN HOSPITAL SUNDAY FUND.

The following are some of the principal amounts received at the Mansion House, or notified directly to us as having been collected, on behalf of the Metropolitan Hospital Sunday Fund up to Tuesday evening last, when the sum paid in exceeded £23,500. It seems doubtful at present whether the result of the collections in the churches will be equal to that of last year. The incumbent of a well-known West-End church, in deploring the decreasing contributions from his church, attributes the falling-off to the "week-end" *habit; and in this connexion we hear of a suburban golf* links where the "whip-round" amongst the golfers had the result of realising more than the collection in the neighbouring church :—

ROYAL COLLEGE OF SURGEONS OF ENGLAND.

An ordinary meeting of the Council was held on June 13th, Mr. Henry Morris, the President, being in the chair.

A report was received from the deputation to the Lord President of the Privy Council concerning the representation of the Members on the Council of the College. The deputation reported that it had placed the views of the Council before the Lord President. The deputation consisted of the President, the Vice-Presidents, Mr. Howard Marsh, Mr. H. T. Butlin, and Mr. A. Pearce Gould.

The Board of Examiners in Anatomy and Physiology for the Fellowship reported that at the recent first examination for the Fellowship 113 candidates presented themselves, of whom 37 were approved.

The Court of Examiners for the Fellowship reported that 63 candidates presented themselves for the final Fellowship examination and that 26 candidates had passed.

On the report of the Board of Examiners in Dental Surgery it was resolved to issue Licences in Dental Surgery to the 26 candidates found qualified.

On the recommendation of the Board of Examiners in Dental Surgery it was resolved :—

1. That Colonial dental practitioners who have completed a course of not less than three years' instruction in mechanical dentistry and who have been registered in British Colonies under conditions which do not require the passing of a recognised preliminary examination, be admitted to the examinations for the Licence in Dental Surgery, provided they pass the required preliminary examination in general education and complete the course of study required by the regulations at a recognised medical school and hospital and at a recognised dental school and hospital.

2. That a candidate who possesses a registrable dental qualification be admissible to re-examination without producing certificates of additional study.

It was further resolved :—

That the following regulation recently adopted by the Royal Colleges in regard to Conjoint candidates do also apply to dental students and be incorporated in the regulations for the Licence in Dental Surgery :—

A candidate must present himself for examination in chemistry and physics together (unless he claims exemption from one of them) until he has reached the required standard to pass in both, or in one of these parts, but he will not be allowed to pass in one part unless he obtains at the same time half the number of marks required to pass in the other part.

It was resolved to close the library during September and October next for the purpose of redecoration.

The following appointments as examiners were made :— Elementary Biology : Thomas George Stevens and H. W. Marett Tims. Anatomy under the Conjoint Board : W. H. Clayton Greene, Arthur Robinson, and William Wright. Physiology under the Conjoint Board : Bertram Louis Abrahams and John Beresford Leathes. Anatomy for the Fellowship : Christopher Addison, W. McAdam Eccles, Arthur Keith, and Alfred Harry Young. Physiology for the Fellowship : Thomas Grigor Brodie, George Alfred Buckmaster, Charles F. Myers-Ward, and W. H. Thompson. Midwifery under the Conjoint Board : A. H. N. Lewers, H. J. M. Playfair, W. Rivers Pollock, and W. W. H. Tate. Diploma in Public Health : Part. I., Harold R. D. Spitta ; Part II., H. Timbrell Bulstrode.

The President reported that Professor William Wright had duly delivered a course of three Hunterian lectures on the Prehistoric and Early Historic Inhabitants of England.

In pursuance of the wishes of the Royal College of Physicians of London it was resolved that the committee of management should be authorised to enter into negotiations with the examining bodies with a view to secure the necessary rearrangement of the curriculum suggested by the Midwifery Curriculum Committee in order to obtain two and a half years for the clinical portion.

A letter was read from the Secretary of the London School of Medicine for Women forwarding a final list of 64 additional signatures to the petition for the admission of women to the examinations of the College, making a total of 2792 signatures.

A letter was read from Lieutenant-Colonel Sir J. Fayrer, R.A.M.C., thanking the Council on behalf of Lady Fayrer and all the members of the family for sympathy and condolence on the death of his father, Sir Joseph Fayrer, Bart.

The President reported that a meeting of Fellows would be held at the College on Thursday, July 4th next, for the election of four Fellows into the Council in the vacancies occasioned by the retirement in rotation of Sir John Tweedy, Mr. H. W. Page, Mr. C. W. Mansell Moullin, and Mr. F. S. Eve, of whom Sir John Tweedy did not offer himself for re-election.

A vote of thanks was given to Sir John Tweedy for his long and zealous services to the College.

THE RED CROSS CONFERENCE.

The Eighth International Red Cross Conference was opened at the Examination Hall, Victoria Embankment, London, on June 11th under the presidency of Field Marshal Lord Roberts. In opening the proceedings Lord Roberts said that since the British Red Cross Society was established in 1870 by the late Colonel Lord Wantage, V.C., no less than half a million of money had been expended in providing comforts for soldiers and sailors in hospital. Of this sum £162,000 were spent during the war in South Africa. After expressing the hope that the deliberations of the delegates would result in further developing the methods for alleviating the sufferings unavoidable during a state of war, he read a letter from the Queen, the President of the British Red Cross Society, in which Her Majesty welcomed the first international meeting on British soil, and also a telegram from the Empress of Russia wishing success to the labours of the Conference. Lord Roberts then read a letter from Miss Florence Nightingale and declared the Conference open.

The Marquis de Vogüé, Baron von dem Knesebeck, and M. G. Ador addressed the assembly, after which the following were appointed vice-presidents : The Marquis de Vogüé (French central committee), Sir F. Treves (English central committee), Sir John Furley (Great Britain), Baron von dem Knesebeck (Germany), Prince Hugue de Dietrichstein (Austria), Major-General C. H. Arendrup (Denmark), Colonel William Cary Sanger (United States), Count André de Csekonics (Hungary), Count Rinaldo Taverna (Italy), Baron Takeo Ozawa (Japan), Baron de Hardenbroek de Bergambacht (Holland), M. de Martens (Russia), and M. Ador (International Committee). M. Edouard Naville was appointed general secretary with the following as secretaries : M. Tasson (Belgium), M. Wunderlich (Germany), M. Pérouse (France), M. Neiss (Switzerland), Dr. Calatraveno (Spain), M. Motzfeldt (Norway), M. Ackerman (Sweden), and Dr. Bikélas (Greece).

On June 12th the delegates met under the chairmanship of the Marquis de Vogüé. After some discussion it was decided that the income of the Empress Augusta Fund, which amounted to about £200 a year, should be devoted to the establishment of travelling scholarships so that selected members of the German Red Cross societies could visit different countries and investigate the methods followed by other societies. By this means the next International Conference in 1912 will have a body of experts in international questions affecting the Red Cross.

M. de Martens submitted a report from the Russian central committee on the subject of the succour of prisoners of war, and after considerable discussion the following was adopted as a resolution :—

The Eighth International Red Cross Conference expresses the opinion that Red Cross societies should recognise that, by force of circumstances, they are obliged to render assistance to prisoners of war subject to the stipulations of the Hague Convention of 1899 and within the limits prescribed by the laws and customs of their countries. The Conference takes cognisance of the declaration of the International Committee of Geneva, offering to act, in case of need, as intermediaries between the central committees of different countries.

On June 13th the Conference resumed its deliberations when the Marquis de Vogüé again presided.

M. Ador read a communication from Dr. Ariga of the Japanese Red Cross Society offering Japanese hospitality for the next International Conference.

General Priou, a member of the Union des Femmes de France, read a paper on the Place and Part of Women in Sanitary Establishments and Hospitals in Time of War. He proposed, in the name of the central committee of the French Red Cross, that the Conference would express the hope that, in all nations, the greatest efforts should be made to bring the masses to recognise and to understand well the necessity of employing women in the territorial hospitals in time of war and of imparting preliminary instruction to them from the material as well as from the moral point of view. The proposition was unanimously agreed to.

Mr. G. H. **MAKINS**, C.B., member of the council of the British Red Cross Society, read a paper on the Rôle of Red Cross Societies during Maritime War. He said that the nature and extent of the aid which could be given by such societies during a naval war was a question of extreme difficulty, partly from the conditions attendant on such warfare and partly from the want of sufficient practical experience. In regard to the general administration of hospital ships, it was desirable that in every respect, as to discipline, equipment, and rations, all hospital ships should be on an identical footing. Medical officers and male and female nurses would certainly be needed in a great war in numbers far above that which any navy could possibly supply. The requirements in regard to the provision of stores and dressings differed little from those of military warfare, but it had to be borne in mind that dressings suitable for military first aid were quite different from those needed in naval campaigns, where the rarity of rifle wounds and the frequency of extensive shell wounds, burns, and scalds rendered a much larger type of dressing a necessity.

Baron **TAKEO OZAWA** (Japan) contributed a paper on the work of the Japanese Red Cross Society. He said that according to military reports there were in the late war 220,812 wounded and 334,073 sick Japanese soldiers and 77,809 sick and wounded Russian prisoners. Deducting from this the number of those who died on the field or were missing, the approximate number of patients which the Army Medical Service had to take care of during the war was 580,000. The Army Medical Corps and the relief corps of the Red Cross Society always worked side by side in the same hospitals, and the relief corps of the society, in the area of operations, on board ship, and in the home territory gave aid to the same patients at different stages of their treatment. In almost all the hospitals on the line of communications and at home the relief corps was entrusted with the treatment of severe medical and surgical cases and infectious diseases, and only the Red Cross Society's nursing *personnel* was used in hospital ships. The Japanese army and navy had no female nurses in their organisations. The two hospital ships of the society were specially built for the purpose of being hospital ships and their transport column was a new organisation having no equivalent in the army. For the whole work of relief during the war the society employed 5170 persons, who were organised into 152 relief corps, and spent a little over half a million pounds sterling.

Motions to the following effect were adopted:—

> (1) The experience of the Russo-Japanese War confirms the urgency of the organisation of a network of stores of sanitary material in time of peace, (2) in order that this organisation may rise to the height of the object proposed, it is necessary that it should be directed by a competent organ, which would be kept constantly informed concerning scientific and technical progress, (3) the renewal of the sanitary material will be effected by the sale of the said material to the hospitals and communities under the control of the representatives of these institutions.

The Marquis **DE VOGÜE** again presided on June 14th.

Dr. **FERRIÈRE** (France) brought up the report presented by the International Committee on the participation of the Red Cross in the struggle against tuberculosis. It stated that Red Cross Societies should aim at (1) obtaining from the military authorities the communication of medical reports concerning men refused as recruits as tuberculous or suspected of becoming so, as well as those concerning soldiers who had become tuberculous in the service and had been discharged on that account; (2) obtaining, so far as possible, by the intermediary of the military and civil authorities that persons belonging of right to the army but discharged as a measure of military prophylaxis owing to tuberculosis should not become itinerary centres of tuberculous contagion in the civil population; (3) the putting of Red Cross Societies in relation with organisations, official or private, competent to assure to tuberculous persons discharged from the army care, assistance, and supervision both in their own interest and in that of general prophylaxis; and (4) direct intervention, when necessary, in the aid given to those eliminated from the army, either by the creation of institutions *ad hoc*, sanatoriums, labour colonies, agricultural colonies, or invalid asylums, or the supervision of the patients in their own families, whether by subventions in money, *matériel*, or *personnel* given to the existing anti-tuberculous institutions. After some discussion it was unanimously resolved that it was desirable that Red Cross Societies should take part in time of peace in the effort to combat tuberculosis, by devoting their attention more particularly to men refused as recruits as well as to soldiers eliminated from the army as tuberculous, or suspected of becoming so. In this respect the support of the civil and military authorities was necessary to realise an efficacious prophylaxis.

The Marquis **DE VOGÜÉ**, as President of the Central Committee of the French Red Cross, read a paper by Professor Félix Guyon, which dealt with the question of good dressings for wounds. In the course of the paper the writer paid a very high tribute of praise to Lord Lister. He proposed (1) the organisation in the army and the civil population of theoretical and practical instruction in regard to the dressing of wounds, and the spreading by that teaching of measures which would protect the people and things from contamination; and (2) a special study of the measures which in time of war, as in time of peace, assure to the wounded the application of a dressing made as quickly as possible, in conditions which obviate the danger of infection. These proposals were agreed to and the members of the Conference rose as a mark of respect for the name and work of Lord Lister.

The concluding sitting of the Conference was held on June 15th. In the afternoon the delegates were received by the King and Queen at Buckingham Palace.

THE EXHIBITION.

In connexion with the Conference an exhibition of Red Cross appliances was held at Prince's Hall, Earl's Court. The first day, June 11th, was devoted to a private view by the delegates and the press, but an unexpected visit by the Queen, who was accompanied by the Queen of Denmark and Princess Victoria, gave great satisfaction to the exhibitors. Princess Christian and Princess Victoria of Schleswig-Holstein visited the exhibition on June 14th.

Part of the exhibits were sent by the various Red Cross Societies in order that delegates might become acquainted with the work of the different national societies and part were sent in for competition for prizes established in 1902 by the Empress Marie Féodorovna of Russia. It was hoped that by opening the exhibition free to visitors to the Earl's Court Exhibition for a few days a stimulus would be given to public interest in Red Cross work, but it is to be feared that from this point of view the exhibition was not an unqualified success. With few exceptions the exhibits were overcrowded and it was almost impossible for the general public to gain any very clear idea of the work which the Red Cross Societies accomplish.

The German section was well represented, the individual exhibits being very large but of varying degrees of excellence. A notable feature of this section was the large number of improvised first aid appliances. America, Austria, Denmark, Holland, France, Mexico, Italy, Japan, Russia, and Switzerland showed appliances of varying degrees of merit. Among the exhibits of the Russian Red Cross Society was the interesting model of a hospital train made under the direction of the senior, Dr. Madame Affanasieff and of the Sister of Mercy Olive. The original of the model was used in the late Russo Japanese war and consisted of goods wagons converted into a travelling hospital. Much ingenuity is shown in the fitting up of the wagons which, of course, were never intended for the transport of wounded men. Some other appliances actually used at the seat of war were also shown.

Among the private firms and individuals who exhibited in the foreign sections Messrs. Utermohlen and Co. (Amsterdam) had a simple and useful first-aid dressing which folds into a packet 2 by 1½ by ½ inches. It is so folded that the surface intended for contact with a wound cannot become contaminated with foreign matter before use. Under the ægis of the Swiss Red Cross Society Mr. D. Hommel showed an ingenious apparatus with two bicycles for carrying wounded. In the same section two stretchers mounted on bicycle wheels were shown by Dr. W. Sahli. These would appear to be of great use in certain circumstances. Messrs. Weber (agents, H. Surbeck and Co., Cheapside, London, E.C.) exhibited a stretcher adopted by the Swiss army which divides into two parts, each of which weighs 10 pounds and is carried folded up by an infantry soldier and slung over the shoulder like a rifle. All parts are interchangeable and the stretcher is of a very practical nature.

In the British section Sergeant-Major H. Barratt had an interesting collection of appliances the outcome of his experiences in the South African war. They are all designed with the object of facilitating the carrying of wounded men and of minimising pain by reducing jolting and vibration, A combined stretcher and sling carrier and a hammock stretcher are as simple as they are likely to be useful, while a spring bracket to support stretchers should prove of great service to wounded when travelling over rough roads in carts or on the floors of railway wagons. A portable stretcher is so constructed that the patient can be laid upon a canvas sheet and the stretcher built round him. All materials likely to be required for first aid are carried in the handles of the stretcher, which are hollow. Messrs. J. and A. Carter (New Cavendish-street, London, W.) exhibited a specially designed field ambulance and two two-wheeled ambulances, the "Carrofax" and the "Salvator." All are fitted with their patent Rastilon suspensory automatic weight-adjusting springs which were described in THE LANCET of July 28th, 1906, p. 236. The field ambulance is worthy of special note on account of the ease with which it can be dismantled and the small space into which it can be packed. The "Salvator" street ambulance has, we understand, been in use by the City police for the past nine months and has given entire satisfaction. Major R. H. Luce, R.A.M.C. (Volunteers), showed a single-wheeled stretcher mounted on a single bicycle wheel for use with the ordinary British army stretcher. Colonel H. G. Hathaway, R.A.M.C., Colonel Valentine Matthews, R.A.M.C. (Volunteers), and Major W. Kirkpatrick had several interesting exhibits, while Major E. H. Richardson showed two dogs for use in searching for wounded men. They are the result of a cross of specially selected breeds and have been found of great use in finding men in places likely to be overlooked by stretcher bearers, especially in night attacks. They carry first-aid dressing and stimulants. Such dogs, we understand, have been adopted by several of the continental armies and were used during the late Russo-Japanese war. Messrs. Leslie, Limited (5, Lloyd's-avenue, London, E.C.), exhibited their various dressings, and the St. John Ambulance Association showed a military ambulance wagon which can be used for either civil or military purposes and two litters of an improved type which have a like double use. Messrs. Henri Simonis and Company (Norfolk-street, London, W.C.) showed their ambulance cycle. When folded up it is an ordinary bicycle on which an ambulance man can travel quickly to the scene of an accident. It can be transformed into a two-wheeled ambulance and attached as a trailer to a bicycle. The same firm exhibited a collapsible stretcher, the "Valada," the sides of which are made after the principle of lazy tongs. It weighs about 12 pounds and can be packed into a small compass and carried like a knapsack. Mr. J. Lynn Thomas, F.R.C.S., amongst other exhibits showed a portable operation table. An exhibit that attracted much attention was the universal splint devised by Sir Frederick Treves and shown by Messrs. Evans and Wormull, 31, Stamford-street, London, S.E. The material consists of aluminium rods fitted with flattened staples at intervals of three inches. These are made in lengths of five feet and can be bent to any form. The splints are made by cutting the rods into suitable lengths to form lateral pieces and connecting them by cross bands of aluminium. The tools required are a pair of pliers, a slotted block, and a measure.

INDIAN MEDICAL SERVICE: THE ANNUAL DINNER.

THE annual dinner of the officers of the Indian Medical Service was held on June 13th at the New Gaiety Restaurant, London, Surgeon-General Sir Benjamin Franklin, K.C.I.E., being in the chair. The dinner was well attended and as there were no speeches the proceedings were of an informal and very enjoyable nature. The chairman briefly referred to the loss which the service had sustained by the death of Sir Joseph Fayrer and proposed that the sympathy of the officers of the Indian Medical Service then present should be conveyed to Lady Fayrer.

The members present were:—*Surgeon-Generals:* A. M. Branfoot, C.I.E., W. B. Beatson, G. W. R. Hay, and L. D. Spencer. *Colonels:* C. W. Carr-Calthrop, W. E. Oates, W. H. Henderson, D. E. Hughes, C. H. de la Ferté Joubert, and W. A. S. Wynne. *Lieutenant-Colonels:* A. Alcock, E. Bovill, Sir R. Havelock Charles, K.C.V.O., S. H. Dantra, P. J. Freyer, W. Gray, E. R. Johnson, G. F. A. Harris, H. Herbert, D. P. Macdonald, T. H. Pope, C. L. Swaine, W. H. Thornhill, J. F. Tuohy, and H. R. Woolbert. *Majors:* G. T. Birdwood, W. H. Caldwell, J. Davidson, A. L. Duke, T. W. A. Fullerton, T. A. Granger, P. B. Haig, S. Hassan, J. B. Jameson, C. A. Johnston, H. G. Melville, W. Molesworth, A. H. Nott, P. W. O'Gorman, L. Rogers, P. C. H. Strickland, and B. G. Turner. *Captains:* H. Ainsworth, A. Fenton, J. K. S. Fleming, G. Harkness, J. H. Horton, R. W. Knox, J. C. G. Kunhardt, Hayward Pinch, F. C. Rogers, R. Steen, E. O. Thurston, J. N. Walker, E. L. Ward, J. W. Watson, and W. S. Willmore. The guests present were Sir Thomas Barlow, K.C.V.O., Dr. Dawson Williams, and Dr. R. A. Young.

MEDICINE AND THE LAW.

Lord Howard de Walden v. Eastes.

IN the High Court of Justice on June 11th there was concluded the case of Lord Howard de Walden *v.* Eastes. The action was brought to restrain the defendant, George Leslie Eastes, M.B. Lond., M.R.C.S. Eng., a medical practitioner, from carrying on a laboratory of pathology at 62, Queen Anne-street, W., on the ground that the carrying on of this laboratory constituted a breach of covenant. The lease was granted in 1893 by the trustees of the Portland Estate to John and Mary Anne Lintott and contained a covenant that the lessees would not, without the previous written consent of the lessors or reversioners, permit or suffer to be used or exercised in or upon the said premises any trade or business whatsoever, but should and would use and occupy the same as and for a private dwelling-house only, except that the same might be used for residential or professional chambers or for offices; and should not, without such consent as aforesaid, make any alteration of or upon the said premises, or do or suffer anything which should be or tend to the annoyance, nuisance, or damage of the person or persons for the time being entitled in reversion or his or their tenants. In 1901 the Lintotts sublet the basement of the house to the defendant who established there a pathological laboratory. This came to the ears of the agent of the estate who wrote to the Lintotts and called their attention to the covenant. After some argument, in September, 1901, a licence was granted to the Lintotts by which they were empowered to allow the defendant "to carry on microscopical tests of fluids of the human body in the basement portion of the said premises and to affix one name-plate outside the said premises, to contain the name of the said George Leslie Eastes only, …… but on condition that no animals are kept on the said premises for the purposes of experiments, and that no biological tests or inoculation be carried on there, and that nothing be done or allowed upon the said premises which shall cause any injury, nuisance, damage, or annoyance to the licensor, his heirs, or assigns, or his or their tenants." There was a further condition enabling the licence to be revoked or withdrawn by three months' notice and it was provided that on the expiration thereof "the said premises shall immediately cease to be used for the purposes hereinbefore authorised." John Lintott died in 1906 and Mary Anne Lintott assigned the premises to the defendant for the remainder of the term, whereupon he altered the ground floor for use as a laboratory and put up two name-plates in addition to that bearing his own name. The plaintiff alleged that by these acts the defendant had broken the terms of the covenant and had exceeded the terms of the licence, and therefore in November, 1906, the plaintiff gave notice to revoke the licence. Mr. Justice Swinfen Eady, in giving judgment, referred in a most sympathetic manner to the value of the work which the defendant had been carrying on. There was no suggestion of improper advertisement but the whole question was a legal one—namely, whether useful and beneficial as the work of the defendant was, he was legally entitled to carry it on at 62, Queen Anne-street. He had broken his licence in that he had extended the work from the basement to the ground floor and had put up more than one plate and one name. He would not draw any distinction between different branches of the defendant's work. He was doing what the licence authorised but what he was precluded from doing if the licence were determined and as it has been determined he was not entitled to carry on the work. The plaintiff was entitled to an injunction perpetually restraining the defendant during the continuance of the lease from using the premises as a laboratory of pathology and the costs would follow the event. The operation of the injunction would, however, be suspended over Sept. 29th next to give the defendant time to make arrangements.

We sympathise with Dr. Eastes in his difficulties but we fear that according to the terms of the covenants into which he had entered he placed himself in a wrong position in making the alterations and in acting as he did. It may be that now that the law has declared itself on the side of the landlord Lord Howard de Walden may see fit to allow the work of Dr. Eastes to be carried on as heretofore. It would appear, however, that the authorities of the Portland Estate have recently adopted what may be called a plan of campaign against door plates, for we understand that medical men who have recently gone to reside on the estate have not been allowed to affix such plates to their doors.

Professional Misconduct.

The Court of Appeal gave judgment on June 12th in Hill *v.* Clifford, Clifford *v.* Timms, and Clifford *v.* Phillips—three cases of great importance to the medical profession. There is one important point common to all the three cases. The cases raised a question as to "professional misconduct" and as to the effect of an order of the General Medical Council under the Dentists Act, 1878. The cases originally came before Mr. Justice Warrington. In Clifford *v.* Timms articles of partnership between the plaintiff Clifford and the defendant Timms, who were dentists, provided that if either partner were at any time during the partnership guilty of professional misconduct or discreditable action the other partner would be at liberty to determine the partnership. The defendant gave the plaintiff written notice to determine the partnership upon the ground that he had been guilty of professional misconduct. It was proved that the plaintiff was a shareholder and director of a company which carried on a dental business and which employed unregistered persons to attend patients, and which advertised by means of pamphlets. The General Medical Council, acting under the Dentists Act, 1878, made an order upon the report of a committee, directing the Registrar to erase from the Dentists Register the name of the plaintiff upon the ground that it had been proved that he had been guilty of conduct which was "infamous or disgraceful in a professional respect" within Section 13 of the Act. The defendant tendered in evidence the order of the Medical Council and the report of its committee to show that the plaintiff had been guilty of professional misconduct within the meaning of the partnership articles. Mr. Justice Warrington held that the evidence was not admissible and that upon the facts proved the plaintiff was not guilty of professional misconduct within the meaning of the articles. Before dealing with the judgment in the Appeal Court, it may be observed that Isidore and Ruby Clifford, being registered dentists, had entered into three separate partnerships with Hill, Phillips, and Timms for carrying on the profession or business of dentists and the actions related to the right of these three persons to determine the several partnerships on the ground that the Cliffords had been found guilty of conduct which was "infamous or disgraceful in a professional respect," and had thereupon been removed from the Register of Dentists. It was contended on behalf of the Cliffords that the order of the Medical Council was *res inter alios acta* and not admissible in evidence to prove that they were guilty of professional misconduct. This contention was adopted by the learned judge in the court below, but the Master of the Rolls in the course of his judgment in the Court of Appeal said: "I cannot agree with this view. I think the order is admissible as evidence of the existence of conduct which was 'infamous or disgraceful in a professional respect,' the proof of which fact was essential to the validity of the order of the General Council. In my opinion the order of the General Council should be treated on the same footing as an inquisition. Unless, and until, evidence to the contrary is given the order suffices to prove that the Cliffords were guilty of statutory misconduct. No evidence was given by the Cliffords to rebut this *primâ facie* evidence. I may add that I doubt whether it is competent to any court to review a declaration by the General Council that an act of a particular kind is 'disgraceful conduct in a professional respect,' even though it may be competent to review the decision that a certain individual has committed an act of that particular kind. The result is that, in my opinion, the judgment appealed against must in each case be reversed. Judgment in Hill's action must be given for the relief asked by the claim, and the two actions brought by the Cliffords against Phillips and Timms must be *dismissed*. The Cliffords must pay the costs in the court below and in this court of each action." It has been held that the General Medical Council is constituted the sole judge of whether a medical practitioner has been guilty of infamous conduct in a professional respect and the court will not interfere where the Council has found anyone guilty after due inquiry. (*Ex parte* La Mert, 4 B. & S. 582.) It would seem that the General Medical Council is bound to give the accused person an opportunity of being heard in his defence, but such person is not entitled to demand to be allowed to appear by counsel. (R. *v.* the General Council, 30 L. J. Q. B. 201.) It is further provided by the Medical Acts that if any of the recognised colleges or medical or surgical bodies at any time exercise any power which they possess by law of striking off from the list of such college or body the name of any one of their members, such college or body shall signify to the General Medical Council the name of the member struck off. A person's name may not, however, be erased from the Register on the ground of his having adopted any theory of medicine or surgery.

THE LANCET, *SATURDAY*, June 20th, 1829.

STATE OF THE MEDICAL PROFESSION.

"Non ignara mali, miseris succurrere disco."—*Virg.*

To the Editor of THE LANCET.

SIR,—The observations of H. W. D., in No. 299 of your valuable Journal, have directed my attention to a subject which has long and frequently been matter of painful musing to me—the unprotected, the unbefriended state of the Medical Profession. The remarks of a "Medical Benedick," in a former Number, on the same subject, I had hoped, would have excited, long ere this, the dormant sympathy of its listless members, and have aroused towards their unfortunate and sick-at-heart brethren, those kindly feelings of commiseration which their situation is so well calculated to call forth. Deeply as I, individually, have deplored the apathy which, dwelling in the bosom of its more fortunate members, have allowed these appeals, strong and energetic as they have been, thus to have subsided into oblivion, unnoticed and unheeded, I have hesitated to answer them myself, in the earnest hope, that amongst the hundreds that exist, many voices more persuasive, and pens more influential than my own, would have enlisted themselves in a cause so grateful to the best and noblest feelings of humanity. But alas!

> "Rari quippe boni: numero vix sunt totidem quot
> Thebarum portæ, vel divitis ostia Nili."

These appeals, in behalf of the forlorn and friendless, have failed in making an impression on the hearts of those to whom they were addressed—the medical profession; but I sincerely trust, for its reputation generally, *that the silence which its members* have hitherto observed on the subject, is more the result of want of reflection and ignorance of the miseries it is proposed to alleviate, than cruel and wanton indifference to the sufferings of their professional brethren. Let them hear from me, that there are, at this moment, *hundreds* of these brethren, once as affluent as themselves, once as vigorous, and even now, perhaps, of as *high acquirements as* themselves, pining, many of them with a wife and family, in the very depths of want and misery! I have in my eye, at this moment, a highly talented M.D., with an amiable wife and two accomplished daughters, thus sinking beneath the blight of misfortune, unprotected, unbefriended, and unheeded—eking out their bitter moments in an obscure garret, with naught but their *religion to comfort* them. But this is not a solitary instance; hundreds, I doubt not, might be mentioned, were it our business to seek them out. Yet is it not horrible that a fate like this should await those members of the community whose lives are spent in administering to the relief of suffering humanity—who sacrifice health and comfort to its necessities—whose lives are *devoted to a species of* civil slavery, which knows neither rest nor *intermission!* The members of the medical profession, unlike all others, are dependent for support no less on their moral than on their professional character; their duties, arduous as they are, afford them, generally, but the bare means of supporting their characters as gentlemen; yet they are obliged, by the narrow-minded feelings of the public, on whom they are dependent, often to enter, prematurely, into obligations the most sacred, and to incur responsibilities the most imposing, lest they labour under disabilities which would render futile their education and attainments. They are subjected, by their investigations of the intricacies of disease, to the dangers of self-destruction by inoculation, or to the sacrifice of health in their devoted attention to their duties, for there is no source of disease in the human body so fertile as that emanating from the harassed state of mind inseparable from the anxieties attendant on those duties. Yet from these, from misfortune, from faculties impaired by age, *we* have no refuge; all other classes enjoy theirs, but we must, with prophetic sagacity, depend alone on uninterrupted health and prosperity to enable us to fulfil the many and sacred obligations our destinies ordain us to incur!

Yet is it not monstrous, that amongst men so enlightened as those which the medical profession numbers in its ranks, misery unalleviated, and misfortune unbefriended—talent unfostered, and labour unrequited—should thus be permitted to exist?—Shall we, on whose sympathy and kindly feelings a greater demand is made than on any other class of men, remain, in the winter of our days, the only beings incapable of arousing, in the breasts of our brethren, those feelings of compunction and commiseration which so readily flow through all other channels? It must not be. If we would not draw down on our devoted heads the maledictions of the broken heart, and the curses of exhausted misery—if we would avoid the hatred and contempt of the more feeling portion of society, of those who are capable of appreciating the cruelty of thus forsaking, in the hour of need, our fellow-labourers—we must hasten (we have delayed too long) to provide them shelter from the passing storm, and a harbour, within whose welcome precincts their shattered barks may ride in safety.

> "Solvite corde metum, Teucri, secludite curas;
>
> Auxilio tutos dimittam, opibusque juvabo."

The importance of this subject leads me to hope, that it may forthwith be taken up by far abler pens than mine; should it not, however, I shall take the liberty of submitting to your notice the means I conceive to be the best calculated to carry this grand object into effect.

I am, Sir,
Your obedient servant,

June 1. Σ.

VITAL STATISTICS.

HEALTH OF ENGLISH TOWNS.

In 76 of the largest English towns 6771 births and 4026 deaths were registered during the week ending June 15th. The annual rate of mortality, which had shown a continuous decline from 17·9 to 13·7 per 1000 in the ten preceding weeks, further fell to 13·1 in the week under notice. During the first eleven weeks of the current quarter the death-rate in these towns has averaged 15·5 per 1000, the rate in London during the same period being 15·0. The lowest annual death-rates in the 76 towns during the week were 3·9 in Smethwick, 4·4 in Aston Manor, 5·3 in Bournemouth, and 7·0 in Hastings; the highest rates were 20·0 in Tynemouth, 20·4 in Sunderland, 22·0 in Middlesbrough, and 22·3 in Preston. The 4026 deaths in the 76 towns showed a further decrease of 187 from the numbers in recent weeks, and included 430 which were referred to the principal epidemic diseases, against 474 and 463 in the two previous weeks; of these, 172 resulted from measles, 124 from whooping-cough, 50 from diarrhœa, 37 from scarlet fever, 36 from diphtheria, and 11 from "fever" (principally enteric), but not any from small-pox. The deaths from these principal epidemic diseases were equal to an annual rate of 1·4 per 1000, the rate from the same diseases in London being 1·7. No death from any of these epidemic diseases was registered last week in Cardiff, Brighton, Tottenham, Southampton, Halifax, or in nine other of the 76 towns; the annual death-rates therefrom, however, ranged upwards to 3·6 in Middlesbrough, 3·7 in Walthamstow and in Gateshead, and 4·7 in Hanley. The fatal cases of measles, which had declined from 214 to 193 in the four preceding weeks, further fell to 172 in the week under notice; the death-rates from this disease ranged upwards to 2·5 in Walthamstow, 2·6 in Middlesbrough, 3·3 in Gateshead, and 3·9 in Hanley. The 124 deaths from whooping-cough showed a slight decline from the number in the previous weeks, the highest annual rates therefrom being 1·3 in Leyton, 1·5 in Grimsby, 1·7 in St. Helens, and 2·0 in Stockton-on-Tees. The fatal cases of diarrhœa, which had been 51, 47, and 49 in the three preceding weeks, were 50 last week; the proportional mortality was greatest in Oldham, the rate being 1·1 per 1000. The 37 deaths from scarlet fever were seven in excess of the number in the preceding week, and included 13 in London, three in Manchester, and two each in Liverpool, Leeds, Bristol, and Salford. The fatal cases of diphtheria, which had been 48 in each of the two preceding weeks, declined last week to 36, and included eight in London, three in Sheffield, and three, equal to an annual rate of 1·3 per 1000 in Leyton. Of the 11 deaths referred to different forms of "fever," two occurred in London, two in Stockport, and one in each of seven other towns. The number of scarlet fever cases in the Metropolitan Asylums Hospitals and the London Fever Hospital, which had been 2732, 2824, and 2862 at the end of the three preceding weeks, had further risen to 2937 at the end of last week; 389 new cases were admitted during the week, against 382, 437, and 368 in the three preceding weeks. The deaths in London referred to pneumonia and other diseases of the respiratory organs, which had steadily declined from 412 to 186 in the ten preceding weeks, further fell to 149 in the week under notice, and were ten below the corrected average number in the corresponding period of the five previous years. The causes of 46, or 1·1 per cent., of the deaths registered during the week were not certified, either by a registered medical practitioner or by a coroner. All the causes of death were duly certified in Bristol, West Ham, Bradford, Newcastle-on-Tyne, and 50 other of the 76 towns; the proportion of uncertified deaths, however, showed a marked excess in Liverpool, Birmingham, Sheffield, Hull, and Northampton.

HEALTH OF SCOTCH TOWNS.

The annual rate of mortality in eight of the principal Scotch towns, which had been equal to 16·7 and 19·0 per 1000 in the two preceding weeks, declined again to 17·2 in the week ending June 15th, but exceeded the rate in the 76 English towns by 4·1 per 1000. The rates in the eight Scotch towns ranged from 11·0 in Greenock and 12·6 in Aberdeen to 18·5 in Glasgow and 22·0 in Dundee. The 599 deaths in the eight towns showed a decrease of 61 from the number in the preceding week, and included 83 which were referred to the principal epidemic diseases, against 91 and 109 in the two previous weeks. These 83 deaths were equal to an annual rate of 2·4 per 1000, which exceeded by 0·7 the rate from the same diseases in the 76 English towns; they included 43 which were referred to whooping-cough, 26 to "fever," eight to diarrhœa, five to measles, and three to diphtheria, but not any to small-pox or to scarlet fever. The fatal cases of whooping-cough, which had been 38 and 57 in the two preceding weeks, rose again in the week under notice to 43, of which 30 occurred in Glasgow, seven in Edinburgh, three in Dundee, and two in Aberdeen. The 24 deaths referred to "fever" were two below the number in the preceding week and included 14 cases of cerebro-spinal meningitis in Glasgow, seven in Edinburgh, and two in Leith. The fatal cases of diarrhœa, which had been 14 and 13 in the two previous weeks, further fell last week to eight, of which four were registered in Glasgow and two in Dundee. The deaths from measles, which had been seven in each of the two preceding weeks, declined to five in the week under notice and included four in Edinburgh. The deaths in the eight towns referred to diseases of the respiratory organs, including pneumonia, which had been 82 and 106 in the two preceding weeks, decreased again last week to 91, but were 11 in excess of the number in the corresponding week of last year. The causes of 20, or 3·3 per cent., of the deaths registered during the week were not certified; the proportion of uncertified deaths in the 76 English towns during the same week did not exceed 1·1 per cent.

HEALTH OF DUBLIN.

The annual death-rate in Dublin, which had been equal to 23·1 and 23·9 per 1000 in the two preceding weeks, further

* Including membranous croup.

rose to 24·3 in the week ending June 15th. During the first 11 weeks of this quarter the death-rate has averaged 28·3 per 1000, the rate during the same period being 15·0 in London and 17·6 in Edinburgh. The 182 deaths of Dublin residents registered during the week under notice were three in excess of the number in the preceding week and included 12 which were referred to the principal epidemic diseases, against 17, 13, and 11 in the three preceding weeks; of these, eight resulted from whooping-cough, three from measles, and one from diarrhœa, but not any from small-pox, from scarlet fever, from diphtheria, or from "fever." These 12 deaths were equal to an annual rate of 1·6 per 1000, the death-rates during the same period from the principal epidemic diseases being 1·7 in London and 2·0 in Edinburgh. The fatal cases of whooping-cough, which has been ten, eight, and four in the three previous weeks, rose again to eight in the week under notice, while the deaths from measles declined to three, having been four and six in the two preceding weeks. The 182 deaths from all causes in Dublin last week included 23 of children under one year of age and 43 of persons aged upwards of 60 years; the deaths of infants slightly exceeded the number in the preceding week, while those of elderly persons showed a decline. One death from violence and five inquest cases were registered; and 75, or 41 per cent., of the deaths occurred in public institutions. The causes of 11, or 6 per cent., of the deaths in Dublin last week were not certified; in London the percentage of uncertified deaths was 0·3, and in Edinburgh it was 4·6. The 140 deaths registered in Belfast during the week under notice included 15 which were referred to cerebro-spinal fever or cerebro-spinal meningitis.

VITAL STATISTICS OF LONDON DURING MAY, 1907.

IN the accompanying table will be found summarised complete statistics relating to sickness and mortality in the City of London and in each of the metropolitan boroughs. With regard to the notified cases of infectious diseases it appears that the number of persons reported to be suffering from one or other of the nine diseases specified in the table was equal to an annual rate of 7·1 per 1000 of the population, estimated at 4,758,818 persons in the middle of the year; the rates in the three preceding months were 6·8, 6·6, and 6·9 per 1000 respectively. The lowest rates last month were recorded in Paddington, Kensington, Hammersmith, the City of Westminster, St. Marylebone, and Lambeth; and the highest rates in Shoreditch, Bethnal Green, Stepney, Poplar, Greenwich, and Woolwich. No case of small-pox was notified in London during the month. The prevalence of scarlet fever again showed an increase last month; this disease was proportionally most prevalent in Finsbury, Shoreditch, Stepney, Poplar, Greenwich, and Woolwich. The Metropolitan Asylums hospitals contained 2777 scarlet fever patients at the end of May, against 2829, 2614, and 2586 at the end of the three preceding months; the weekly admissions averaged 368, against 323, 312, and 332 in the three preceding months. The prevalence of diphtheria showed no variation from that recorded in the previous month; the boroughs in which this disease was most prevalent were Fulham, Chelsea, Poplar, Battersea, Deptford, and Greenwich. There were 933 diphtheria patients in the Metropolitan Asylums hospitals at the end of last month, against 916, 1012, and 946 at the end of the three preceding months; the weekly admissions averaged 121, against 126, 138, and 119 in the three preceding months. Enteric fever showed a considerably diminished prevalence in May compared with that in the earlier months of this year; the greatest proportional prevalence of this disease occurred in Kensington, Chelsea, the City of Westminster, Stoke Newington, and Holborn. The number of enteric fever patients under treatment in the Metropolitan Asylums hospitals, which had been 103, 93, and 66 at the end of the three preceding months, had further fallen to 47 at the end of last month; the weekly admissions averaged only nine, against 16, 13, and 12 in the three preceding months. Erysipelas was proportionally most prevalent in Holborn, the City of London, Bethnal Green, Southwark, and Hackney. The 24 cases of puerperal fever notified during the month included three belonging to Wandsworth, three to Camberwell, and two each to Hackney, Lambeth, and Lewisham. Of the 21 cases notified as cerebro-spinal fever five belonged to Lambeth and two each to St. Pancras, Poplar, Bermondsey, Battersea, and Deptford.

The mortality statistics in the table relate to the dea of persons actually belonging to the various boroughs, deaths occurring in institutions having been distribu among the several boroughs in which the deceased pers had previously resided. During the five weeks end June 1st the deaths of 6405 persons belonging to Lond were registered, equal to an annual rate of 14·0 per 10 in the three preceding months the rates had been 18·4, 15 and 15·8 per 1000. The death-rates last month ranged fr 8·8 in Hampstead, 10·1 in Lewisham, 10·5 in Woolwi 11·7 in Fulham and in Wandsworth, 12·1 in Batters and 12·2 in the City of Westminster, to 16·8 Finsbury and in Poplar, 17·0 in Bermondsey, 17·7 Southwark, 17·8 in Holborn, and 20·2 in Shoredit The 6405 deaths from all causes in London last mon included 698 which were referred to the principal infecti diseases; of these, 234 resulted from measles, 55 from scar fever, 64 from diphtheria, 256 from whooping-cough, from enteric fever, and 79 from diarrhœa. In addition these 698 deaths there were seven fatal cases of cerebro-spi fever, four of which belonged to Lambeth, and one each Fulham, Bermondsey, and Deptford. The lowest dea rates from the principal infectious diseases were recorded the Cities of London and Westminster, and in the boroug of Hampstead, Lewisham, and Woolwich; and the high rates in Stoke Newington, Finsbury, Shoreditch, Bethn Green, and Poplar. The 234 fatal cases of measles were below the corrected average number in the correspondi periods of the five preceding years; this disease was p portionally most fatal in Finsbury, Shoreditch, Popl Deptford, and Greenwich. The 55 deaths from scarlet fe were 10 in excess of the corrected average number; t greatest proportional mortality from this disease occurred Stoke Newington, Hackney, Shoreditch, Bethnal Gree Poplar, and Woolwich. The 64 deaths from diphtheria we slightly fewer than the average; among the various met politan boroughs the highest death-rates from this disea were recorded in Paddington, Fulham, Holborn, Poplar, a Battersea. The 256 fatal cases of whooping-cough show an excess of 60 over the corrected average number; th disease was proportionally most fatal in Kensington, Hamm smith, Stoke Newington, Shoreditch, Bethnal Green, a Bermondsey. The ten deaths referred to enteric fev were equal to only one-half of the corrected average for t corresponding period of the five preceding years; of the ten deaths two belonged to the City of Westminster, two Hackney, and two to Finsbury. The 79 fatal cases diarrhœa showed a slight decline from the corrected avera number; the greatest proportional mortality from th disease occurred in Fulham, Chelsea, the City of Wes minster, St. Marylebone, Finsbury, and Stepney. In co clusion, it may be stated that the aggregate mortality fro the principal infectious diseases in London last month w about 6 per cent. below the average.

Infant mortality, measured by the proportion of deat under one year of age to registered births, was equal 102 per 1000. The lowest rates were recorded in St. Mar lebone, Hampstead, Battersea, Wandsworth, Lewisham, a Woolwich; and the highest rates in Kensington, Hamme smith, the City of Westminster, Islington, Shoreditch, a Bethnal Green.

THE SERVICES.

ROYAL NAVY MEDICAL SERVICE.

THE following appointments are notified:—Surgeons H. W. Hull to the *Pathfinder*, on recommissioning. Civ Practitioners: J. O'Donoghue to be surgeon and agent Baldoyle and Clontarf and A. G. Price at Greystones.

In accordance with the provisions of Her late Majesty Order in Council of April 1st, 1881, Fleet Surgeon Alfre Patterson has been placed on the retired list, with permissio to assume the rank of Deputy Inspector-General of Hospital and Fleets (dated June 11th).

ROYAL ARMY MEDICAL CORPS (MILITIA).

Captain (Honorary Lieutenant in the Army) H. Fo resigns his commission (dated April 9th, 1907).

VOLUNTEER CORPS.

Rifle: 1st Volunteer Battalion, the Leicestershi Regiment: Surgeon-Lieutenant W. F. McAllister-Hewling resigns his commission (dated May 9th, 1907). 3rd Voluntee

Battalion the Essex Regiment: Francis James Warwick (formerly Captain, Royal Army Medical Corps (Volunteers)), to be Surgeon-Captain (dated March 20th, 1907). 1st Hallamshire Volunteer Battalion the York and Lancaster Regiment: Surgeon-Lieutenant W. S. Kerr to be Surgeon-Captain (dated May 7th, 1907). 2nd (Renfrewshire) Volunteer Battalion Princess Louise's (Argyll and Sutherland Highlanders): Surgeon-Lieutenant J. C. Herbertson to be Surgeon-Captain (dated March 19th, 1907).

Royal Engineers (Volunteers): 1st Newcastle-on-Tyne: Wilfred Ernest Alderson to be Surgeon-Lieutenant (dated April 26th, 1907).

ROYAL ARMY MEDICAL CORPS (VOLUNTEERS).

Eastern Command: Woolwich Companies: Lieutenant-Colonel and Honorary Colonel F. L. Stephenson, on completion of his period of service in command, is retired, with permission to retain his rank and to wear the prescribed uniform (dated April 16th, 1907). Major and Honorary Lieutenant-Colonel C. H. Hartt to be Lieutenant-Colonel, and to command under the conditions of paragraph 47, Volunteer Regulations (dated April 16th, 1907).

Scottish Command: Glasgow Companies: Lieutenant W. Bryce to be Captain (dated June 1st, 1907).

DEATHS IN THE SERVICES.

Brigade-Surgeon James Balfour Cockburn, A.M.D., on June 10th, at Guernsey, in his seventy-eighth year. He entered the service in 1854 as assistant surgeon, became surgeon in 1864, and surgeon-major in 1873, retiring in 1882. He served in the Eastern campaign of 1854–55, including the expedition to Kertch and Yenikale, and was present at the siege of Sebastopol (medal with clasp and Turkish medal). The deceased officer was a Provincial Grand Master of Freemasons in the Guernsey and Alderney District.

THE ARMY ORGANISATION SCHEME.

It is certainly worthy of being put briefly on record that the Territorial and Reserve Forces Bill as amended was discussed in the House of Commons on June 17th, when some important concessions in regard to the retention of the militia were intimated to the mutual satisfaction of the Secretary for War and the Leader of the Opposition. The Bill has now been read a third time in the House of Commons and relegated to the House of Lords for further consideration.

Correspondence.

"Audi alteram partem."

SIR FREDERICK TREVES ON THE PROPHYLAXIS OF DISEASE.

To the Editors of THE LANCET.

SIRS,—Certain imperfectly reported observations of mine, made at the opening of the Isolation Hospital for Infectious Diseases at Preston, have been so distorted in certain journals and have been so further misrepresented in a most objectionable advertisement just issued that I should be glad if you would allow me to refute the ridiculous assertions with which I am credited. I am made to say that "patients should leave off taking medicine when they are sick." I need not say that I made no such preposterous observation. What I did say was this—that in dealing with such maladies as typhoid fever, small pox, scarlet fever, and tuberculosis the public would be better advised to adopt preventive measures against those disorders than take medicines when they were sick with them.

From this observation I imagine that no medical man would dissent. I further quoted the following passage from Frankland's "Pasteur" (p. 129): "A day will come when in Berlin, in London, in Paris, man will not die of diphtheria, of typhoid, of scarlet fever, of cholera, of tuberculosis, any more than he dies in these cities to-day from the venom of snakes or the tooth of wolves." My solicitors have received from the authors of the advertisement an assurance that it has been discontinued.

I am, Sirs, yours faithfully,
FREDERICK TREVES.
Wimpole street, W., June 18th, 1907.

THE PUBLIC ATTITUDE TOWARDS CONSUMPTIVES.

To the Editors of THE LANCET.

SIRS,—It is certainly high time that an effort should be made to abate the unreasonable attitude of the public towards consumptives to which you call attention in one of the annotations in a recent issue of THE LANCET. You say, "The knowledge of the communicability of consumption from person to person so long disputed, but now so universally recognised, has resulted in a widespread misconception as to the mode of infection, in virtue of which no little hardship is inflicted upon the unfortunate sufferers from that disease," seeing that they are now, as Mr. W. K. McClure has shown, excluded from many first-class hotels in various health resorts.

I venture to think, however, that the medical profession itself is in the main responsible for this exaggerated attitude on the part of the public, owing to the extraordinary change during recent years in its own point of view in regard to this disease. Thirty years ago phthisis was commonly regarded as a generable affection springing up *de novo* in the individual and only in very exceptionable cases was it believed to be communicated from person to person. But the discovery of the tubercle bacillus soon began to lead to a complete change and to the promulgation of doctrines as to the mode of dissemination of the disease which are now gradually being shown to be erroneous.

Thus for a series of years it has been persistently taught that the disease is spread by contagion only, that it never arises *de novo*, and that its spread from person to person, which is regarded as a common process, is solely through the inhalation of tubercle bacilli contained in dust set free from dried sputa. This doctrine has undoubtedly led to a beneficial campaign against a disgusting practice and to the adoption of very desirable precautions in regard to the sputa. But of late years the experimental investigations of Cadéac,[1] as well as other researches, have shown that "the penetration of air-borne particles into the lungs is difficult if not impossible," while at the same time they have demonstrated how little the dried glutinous sputum lends itself to pulverisation and how soon the bacilli contained therein cease to be infective.

Yet this mode of dissemination, now so much discredited, is stated by you to be the only common mode of the spread of the disease from person to person. You say, "It cannot be too generally known that practically the only means of conveying infection from one person to another is from the drying of the sputum and its dissemination as dust containing tubercle bacilli, if we except intimate personal contact, such as kissing or occupying the same bed." If, however, this formerly supposed common mode of spread is, in fact, extremely rare we must all agree with you when you say—and it is an all-important point—"Given the most simple precautions in regard to the disposal of his sputum by the consumptive the danger of infection is almost non-existent."

Further, if the spread of phthisis from person to person is rare, and if infection through the lungs does not take place save in quite exceptional circumstances, it may well be asked, are we to suppose (1) that this terrible scourge comes to us almost only by way of the alimentary canal from the ingestion of infected milk or flesh, and (2) to suppose with Behring that in multitudes of cases tubercle disease germs taken in during childhood are capable of remaining latent for many years in the system; or (3) shall we admit that we have been much too hasty in throwing aside the old doctrine that phthisis is a generable affection, often arising *de novo*? From the latter point of view we have only to suppose that what prove to be tubercle bacilli are often only some of the common bacilli constantly gaining access to the body which, under special conditions, have undergone modifications in property in this or that tissue. Such possibilities will be found reconcilable with many facts otherwise hard to explain. Thus the present Gresham professor of medicine lately said in a discussion at the Royal Medical and Chirurgical Society (Feb. 26th): "Women in Egypt suckled their children for even two years, and all other milk was boiled, and among the cattle tubercle was rare, yet tuberculosis was common." And in my recently published work on "The Evolution of Life" I have in the last chapter indicated how bacteriologists themselves are finding that in numerous cases there are transitions both in form and in property between non-pathogenic and pathogenic bacteria.

---

[1] Lyon Médicale, Dec. 10th, 1905.

As another instance showing how opinions are beginning to change at the expense of ultra-contagionist doctrines I may say that quite recently Dr. E. C. Seaton has kindly sent me his annual report as medical officer of health of the county of Surrey, in which after a most careful inquiry into the seasonal prevalence and the distribution of typhoid fever in the county he says (p. 39): "I believe that Dr. Pierce of Guildford and other careful observers in our county could furnish Dr. Bastian with examples of typhoid occurring in isolated country dwellings or under conditions where chances of infection could be definitely excluded." Further, he goes on to express his own opinion in these precise terms: "Personally I agree that cases occur from time to time in purely country districts which it is absolutely impossible to connect with any previous case, and which suggest the possibility of new origin (i.e., apart from human infection) through bacilli other than those which are regarded as the invariable specific cause of typhoid." *Mutatis mutandis* that is precisely what I am contending for in regard to phthisis and other communicable diseases.

I am, Sirs, yours faithfully,
H. CHARLTON BASTIAN.
London, June 8th, 1907.

THE MEDICAL SCHOOL OF ST. THOMAS'S HOSPITAL AND THE CONCENTRATION OF EARLY MEDICAL STUDY.

To the Editors of THE LANCET.

SIRS,—At the date of the recent election by the Faculty of Medicine of their representatives on the senate of the University of London, an impression obtained that St. Thomas's Hospital was no longer whole-hearted in support of an Institute of Medical Sciences at South Kensington. This impression is entirely erroneous and in view of the meeting of the faculty summoned for next week it seems desirable that it should be corrected.

St. Thomas's has throughout been consistent in its opinions on this question and still desires to afford its support to the senate in the steps which the University has taken, on the recommendation of the faculty, to establish an institute at South Kensington. The treasurer of St. Thomas's is a member of the committee appointed by the senate to obtain financial help for this scheme; the staff and lecturers continue to give their unanimous support to the proposal; they believe it to be one of the most important steps which can be taken and which are so urgently needed to strengthen the position of the metropolis as the chief centre of medical education in the United Kingdom.

I am, Sirs, yours faithfully,
J. HERBERT FISHER,
Dean of the Medical School, St. Thomas's Hospital.
June 17th, 1907.

BEES' STINGS AND RHEUMATISM.

To the Editors of THE LANCET.

SIRS,—In the course of an inquiry into the relation which I have been led to suppose may exist between certain manifestations of rheumatism and an abnormal production of formic acid in the tissues my attention has been called from time to time to a curious belief which appears to be prevalent in various parts of the country. This very interesting piece of folk lore is to the effect that frequent exposure to the stings of bees (as among bee-keepers) is both protective and curative for rheumatism. My correspondence leads me to conclude that this belief is widely disseminated and is probably familiar to many of your readers.

May I, therefore, be allowed the privilege of making the following inquiries (through your correspondence column) of any of your readers who are sufficiently interested in the question to send me such information as has come within their own knowledge? 1. Have you met with the belief that bees' stings cure or prevent rheumatism? 2. Do you know any case in which a rheumatic subject claims to have benefited in this way as the result of working among bees? 3. Are you acquainted with any reliable evidence which supports or explains the origin of this belief? 4. What were the characters of the "rheumatism" in question?

I am, Sirs, yours faithfully,
E. W. AINLEY-WALKER.
University College, Oxford, June 17th, 1907.

THE SOCIETY OF APOTHECARIES OF LONDON BILL, 1907.

To the Editors of THE LANCET.

SIRS,—This Bill having been passed by both Houses of Parliament now only awaits the Royal Assent to become law. It changes the title of L.S.A. to the more appropriate one of Licentiate in Medicine and Surgery and gives authority to the Society to confer the latter title by diploma on all of its Licentiates who have qualified since June 30th, 1887. Authority is also given to the General Medical Council to enter the new description on the *Medical Register*. Power is given to the Society to restore (with the consent of the Medical Council) the name of any Licentiate who may have been removed from the roll. Heretofore the Society had only the power to remove a name. The cost of obtaining this Act has been considerable and the council of the Association of Physicians and Surgeons of the Society of Apothecaries undertook to raise £250 towards it. Of this sum £222 5*s.* 6*d.* have been subscribed by the Licentiates, £25 was voted by the Association from its funds, leaving a deficit of £2 14*s.* 6*d.* The expenses of collection amount to £13 1*s.* 9*d.*, bringing the total deficit to £15 16*s.* 3*d.* May I ask those Licentiates who have omitted to send a donation to send their contributions to me without delay? It is scarcely fair that the members of the council of the Association who have had all the hard work, and who have already borne more than their share of the expenses, should also be saddled with this deficit.

I am, Sirs, yours faithfully,
A. RIVERS-WILLSON.
42, Wellington-square, Oxford, June 17th, 1907.

HÆMOGREGARINES IN SNAKES.

To the Editors of THE LANCET.

SIRS,—In the abstract of the paper on Hæmogregarines in Snakes (read at the Pathological Society on June 4th) which you published in THE LANCET of June 15th you omitted Dr. C. G. Seligmann's name, although the paper was in fact a conjoint publication. I should be most obliged if you would mention this in your next issue.

I am, Sirs, yours faithfully,
LOUIS W. SAMBON.
Palace Gardens Mansions, W., June 18th, 1907.

THE WEST LONDON HOSPITAL DINNER.

To the Editors of THE LANCET.

SIRS,—In the account of the West London Hospital and Post-Graduate College dinner given in THE LANCET of June 15th, you say it was under the presidency of Mr. E. Lloyd Williams. It is a curious mistake to have made. There is a Mr. E. Lloyd Williams, but I was the chairman of the dinner and am the dental surgeon to the hospital.

I am, Sirs, yours faithfully,
H. LLOYD WILLIAMS.
Upper Wimpole-street, W., June 19th, 1907.

THE ASSOCIATION OF PUBLIC VACCINATORS OF ENGLAND AND WALES.

To the Editors of THE LANCET.

SIRS,—A meeting of delegates appointed by the 37 representative councils of the Association of Public Vaccinators of England and Wales was held in London yesterday. The delegates represented over 3000 members of the medical profession who are public vaccinators and the following was one of the resolutions passed at the meeting:—

> That this representative meeting of the public vaccinators of England and Wales emphatically protests against the provisions of the New Vaccination Order, which suggest the reduction of the existing minimum fees to public vaccinators and points out that, although the Departmental Committee reported that if the public vaccinator were made an officer, only removeable with the consent of the Local Government Board and eligible for superannuation, it might be fair to make some reduction of fees; the new Order not only refuses to the public vaccinator the position which is his just claim, and leaves him still under contract without right of appeal; but also reduces the minimum fees for domiciliary vaccination even lower than the committee suggested.
>
> That in the opinion of this meeting it is impossible for the work to be remunerative at the minimum fees in any district in England and Wales under existing circumstances, and that the proposed reduction

would be an instance of sweating of medical men such as can scarcely be exampled in any other branch of the public medical service.

That this meeting looks with the gravest apprehension upon the effect of such inadequate fees as are suggested, feeling that public vaccination in England and Wales cannot be maintained at its present level of efficiency upon such terms.

I am, Sirs, yours faithfully,
CHAS. GREENWOOD.
Mitre-court-buildings, Temple, E.C., June 19th, 1907.

OF MEDICO-LEGAL INTEREST.

To the Editors of THE LANCET.

SIRS,—On June 8th a patient of mine was taken in labour at 1 A.M. with her first child. Her husband fetched the "nurse" at 2 A.M. who said that she "would not be wanted for hours" and left the house. At 5 A.M., while my patient was standing, the baby was born and fell on the floor, the cord breaking. The poor woman jumped into bed, but neither she, the husband, or an old woman in the house knew how to tie the cord. On my arrival at 5.25 I found there had been a good deal of bleeding from the cord, while there was an extensive bruise on the head of the infant. Had my patient been a single woman and had the baby died it is quite conceivable that her story might not have been believed and she might have had to stand her trial for murder. For this reason I think the case is of sufficient interest to justify record.—I am, Sirs, yours faithfully,

June 11th, 1907. A. G. P.

NEW VACCINATION LEGISLATION.

(BY A PUBLIC VACCINATOR.)

THE two principal officials of the Local Government Board have both won their political positions as paid nominees of two of the most highly organised trade unions in England. Perhaps the finished knowledge of trade unionism possessed by both Mr. Burns and Dr. Macnamara has enabled them to gauge the weakness of resistance of a poorly paid but honourable profession which has not yet stooped to trade unionism. Nothing else could have induced these two gentlemen to compel public vaccinators to work for wages which no member of the Amalgamated Society of Engineers or the School Teachers Union would be allowed by those bodies to accept.

Imagine the storm which would have arisen in the House if Mr. Haldane had proposed to Parliament that the wages of the artisans of Woolwich Arsenal should be suddenly reduced from 30*s.* to 15*s.* per week. But without reference to Parliament Mr. Burns lowers in this proportion the earnings of a large body of men by his own personal authority. For though few of the public know that the "Local Government Board" is a non-existent body which never has met, they were reminded of this fact a few weeks ago by Mr. Burns himself, who stated in answer to a question in the House that the Board had never been convened since it was established and he had no intention of ever convening it. Mr. Burns is the "us" of the new Orders and his decisions, issued as Orders in Council, have the effect of Acts of Parliament. They can only be discussed in Parliament on the Estimates, if they are ever discussed at all, and they may be framed, as in the present instance, in direct opposition to the findings of a committee of his own department.

I am well aware that THE LANCET takes no account of politics, but it is inexplicable that such an autocratic method of bureaucratic administration should commend itself to professing democrats like the supporters of the present Government. There is every reason to doubt that the Local Government Board has any intention of protecting the public vaccinators in their struggle for a decent remuneration. The really important, in fact the only important, clause in the new Order is that which reduces the minimum fee for successful vaccination of an infant from 5*s.* to 3*s.* 6*d.* in country districts and to 2*s.* 6*d.* in urban districts of more than 50,000 inhabitants. It may be urged that these fees are "minimum" fees and that larger sums may be paid (as they are now paid) in excess of those minimum fees. But in spite of the recommendations of the Departmental Committee of 1904 the public vaccinators have been given no permanent tenure of their offices. They are therefore liable to termination of their contracts at a month's notice, and where boards of guardians choose to enforce the minimum rate of pay there is no power to compel them to pay more except the Local Government Board, which is Mr. Burns. The agitation in 1904, which led to the appointment of the Commission on Expenses, clearly showed the attitude which was, and will be, adopted by the bulk of boards of guardians, and I regret to say that the new Order indicates too clearly the attitude which will be adopted by the Local Government Board. Consider the work which has to be undertaken and completed for 2*s.* 6*d.* The public vaccinator has to check off and copy Form H which contains four columns of detail and return it to the vaccination officer, then to fill in and send notice of intended visit to each parent to call by appointment on a given day to vaccinate the child, and revisit the case the week after, as well as to fill in and despatch a certificate, and keep a register (which must be filled up every day) containing 19 columns of details. If the parents refuse his services the vaccinator gets nothing for his trouble. If they are out he must call again, and in many districts they always are out, of *malice prepense*. If the child is unfit to be vaccinated the vaccinator must fill in another certificate and call again. The *minimum* number of visits which must be paid is two; the time occupied in vaccination is at least 20 minutes, for scrupulous antiseptic precautions must be observed; and the outgoings in dressings amount to about 6*d.* per head, and an average of 1*d.* per head in postage. From the evidence laid before the Commission it was clear that an average of three and a half to four visits is made by public vaccinators for every fee which they receive, so that in urban districts these gentlemen are to be paid 6*d.* per visit when their out-of-pocket expenses are deducted; in addition to the time taken to reach the child's home, which averages a quarter of an hour each way, the actual operation takes 20 minutes per case and the clerical work 15 minutes, for after vaccination is complete there are forms to despatch as to result and forms for demanding fresh lymph. A trade union joiner earning 6*d.* an hour is better paid.

The subclause (*e*), Article I., 3, is just in principle but goes too far. Under the original Order of 1898, payment was made for each case of vaccination or revaccination irrespectively of the number vaccinated at one sitting and under one roof. This had practically no bearing upon primary vaccination but had a very important bearing in epidemics of small-pox, when whole families were revaccinated together. Thus a vaccinator who received an extra-distance fee of 7*s.* 6*d.* per head for the journey and operation received £3 7*s.* 6*d.* for revaccinating a family of five persons at the same time. This rate of payment was in most instances excessive. But the extravagance might have been entirely prevented if boards of guardians had been properly alive to their powers and established temporary stations in rural districts. They made no attempt to do so, and the Local Government Board made no attempt to instruct them, with the consequence that during the epidemic of 1901–02 the bills for revaccination in many areas were 300 per cent. higher than they should have been. Owing to its obscurity it will be as well to quote *in extenso* the article which seeks to remedy this undue expenditure, and (if I read it aright) it effects its purpose in a trenchant manner.

> *Article I., 3, (e).*—Except so far as this subdivision otherwise provides nothing in paragraphs (*b*), (*c*), and (*d*) of this subdivision shall apply to any case in which during a period of twenty-four consecutive hours successful vaccination or successful revaccination has been performed by the public vaccinator upon two or more persons at one and the same house, or on any premises (other than the surgery of the public vaccinator) whereon those persons were together present at any time during the aforesaid period.
>
> In every such case the amount to be paid to the public vaccinator shall, in respect of the first person vaccinated or revaccinated, be the sum which being not less than the sum specified in such one of the rules hereinbefore set forth as is applicable to the case of the person is fixed in the contract approved by us, and in force for the time being, or, in any case to which subdivision (1) of Article 5 applies, is fixed by an instrument executed in pursuance of that subdivision, and in respect of every other person vaccinated or revaccinated the amount to be paid to the public vaccinator shall be such a sum as is fixed in the contract approved by us and in force for the time being, or such sum as in any case to which subdivision (1) of Article 5 applies is fixed by an instrument executed in pursuance of that subdivision.

The reference to Article 5 subdivision (1) applies to the article in the Order of 1898, not the present Order, though this fact is not named. If this clause means anything it means that whereas a vaccinator is to get 2*s.* 6*d.* a head for vaccinating at his own house, if he goes elsewhere to revaccinate a family he will only get the 2*s.* 6*d.* for going there and vaccinating the first person and such a sum or the second and other persons as is to be fixed in the ontract. The language may be ambiguous but the inten- ion is obvious; such a sum will be considerably less than s. 6d., at best it will be 1s. 6d. By what species of logic a ee of 2s. 6d. per head is allowed for vaccinating at the vac- inator's own house and a lower fee for travelling an unspeci- ied distance to perform the operation it is difficult to perceive. n Article 3 (*b*) a new rule is issued that children over 12 nonths' old may at the request of their parents be vaccinated elsewhere than at the homes of the children. This is o save 1s. on the procedure, as the vaccinator will only et 2s. 6d. even in rural districts. But the vaccinator before e vaccinates must have regard to the provisions of sub- ection (4) Section 1 of the Act of 1898, which is to the ffect that he must satisfy himself as to the condition of the house in which the child resides. He is therefore expected to nspect the child's home, at whatever distance, and vaccinate for 2s. 6d. Article 6 (*a*) contains a new instruction to vaccina- ion officers the use of which is hardly apparent until he *meaning* is found in the final sentence in Form Q, which reminds the parent that the child will be four months old on a certain date and that unless a certificate be received ealing with the vaccination of the child within a week the child's name will be placed on the list H to be dealt with by the public vaccinator. The final sentence is: "If, however, you should propose some other arrangement for the vaccination of the child I shall be glad to be informed of the same." This is, of course, a clumsy and devious invitation to have the child vaccinated privately in order to lessen the expense of the public service.

In spite of the recommendations of the Departmental Committee that some relief in clerical work should be afforded to public vaccinators none has been given, with the very slight exception of the mechanical rearrangement in certificates B, C, D, and E; in fact, an addition has been made by the auditors of the board to their work of a very irritating character. They are expected to make duplicates of the lists sent them by vaccination officers (Form H) and to send them in with their accounts. This demand by the auditors is in my opinion quite *ultra vires*, as it is not specified in the Orders of 1898. The only attempt in the new Order to relieve the work of the vaccinators is to extend the period within which the child must be visited (after the notice of the vaccination officer that the child has not been vaccinated) from two weeks to four. This relief is practically worthless as regards work which lies at a distance, for the irksome feature of public vaccination is that it must be done by appointment and other work thrown over in its favour if necessary. But neither Members of Parliament nor the officials at Whitehall realise how difficult it is for general practitioners to keep appointments at distances, liable as they are to constant dislocation of any arrangements they may make. Some sensible modification of the clumsy forms of certificates which have been in use for so many years might have been made, but the slight alterations made in certificates B, C, D, and E, and referred to above, are almost valueless. The same useless repetition of places of birth and residence is demanded in spite of the fact that on the same paper is inserted the number of the entry of the child's birth in the registrar's book, which should be sufficient proof of identity in case of dispute.

This Order shows an extraordinary ignorance on the part of the official who issues it of the work performed by vaccinators and ignorance of the immense amount of wasted labour they have to perform and the long distance they often have to travel, for which they get no remuneration. In the scale sanctioned by the late Government this wasted work was considered and a moderate liberality of pay allowed. No attempt has been made to reduce the work, while the fees for urban vaccinators are halved and those of rural vaccinators nearly halved. I have already compared the future wages of the urban vaccinator with that of the second-rate artisan to the advantage of the latter, but the condition of the rural official will in many instances be far worse; the evidence given before the Commission proved conclusively that 30 miles was no uncommon distance to be travelled in connexion with one case. In many districts the minimum fee will be enforced and no support can be expected by the vaccinator from the Local Government Board. The man who is to maintain a stable and drive 30 miles for 3s. 6d. had better abandon medicine and keep a cab. There are many hard-working men in the large towns who have had practically to give up private practice to attend to their duties as public vaccinators; they are more than middle-aged, they can scarcely hope to build up a fresh private practice, and they are suddenly to be deprived of half their incomes with neither notice nor compensation. For they work in black coats and are not paid weekly wages.

THE GERMAN CONGRESS OF INTERNAL MEDICINE.[1]

(FROM OUR BERLIN CORRESPONDENT.)

(Concluded from p. 1666.)

Experimental Investigations on the Production of Leukæmia.

DR. ZIEGLER (Breslau) said that he had made experiments on animals by exposing the spleen to x rays. He found that the destruction of the follicles of the spleen led to an increase of the mononuclear leucocytes in the blood and that the bone marrow underwent a lymphoid hyperplasia. A partial destruction of the spleen also led to myeloid leukæmia, but of temporary duration only. Destruction of the bone marrow, however, did not give rise to leukæmia. He was of opinion that normal blood was the result of a normal correlation between the spleen and bone marrow and that when this correlation became disordered leukæmia was produced. Injury to either of the two led to hyperplasia of the correlative element of the blood.

Estimation of the Quantity of Blood in the Living Body.

DR. PLESCH (Budapest) showed some apparatus which he devised for the purpose of measuring the quantity of blood circulating in the living body. He had arrived at the following results. The quantity of circulating blood in the human subject was 5 per cent., or $\frac{1}{20}$th of the weight of the body. The quantity of hæmoglobin in a healthy adult was 0·7 per cent., or $\frac{1}{140}$th of the weight of the body. Referred to the body weight the quantity of blood was from 7 to 8 per cent. in the dog, from 7 to 10 per cent. in the horse, and from 5 to 6 per cent. in the rabbit. Fat individuals had proportionately less blood than lean ones. For chlorotic patients the proportion varied between 7 and 10·8 per cent. of the body weight, while in anæmia caused by severe hæmorrhage it was from 4·6 to 6·6 per cent. In nephritic patients without œdema the proportion was increased to 9·9 per cent. of the body weight.

The Blood Pressure and the Amplitude of the Pulse in Healthy Persons.

DR. HESSE (Kissingen) using Recklinghausen's tonometer has made investigations of the blood pressure in healthy persons. He found that in the recumbent position the systolic and diastolic pressures were decreased, the diastolic in a higher degree, so that the amplitude of the pulse became smaller. The taking of food and fluids increased the blood pressure and the frequency of the pulse, showing that the work done by the heart was increased. On standing up the systolic pressure was less increased than the diastolic pressure, the amplitude of the pulse becoming smaller. Active exercise of short duration caused an increase of the frequency of the pulse and the diastolic and systolic blood pressure, the work done by the heart therefore becoming greater.

The Influence of Adrenalin on the Heart and the Vessels.

DR. GROBER (Jena) said that he had administered adrenalin to guinea-pigs for the purpose of examining its influence on the heart and especially on the left ventricle. He found that a long-continued administration of adrenalin produced in addition to other alterations in the organs hypertrophy of the heart. The thoracic aorta became rigid by necrosis of its walls and hypertrophy of the left ventricle was the consequence. This experiment showed that an isolated necrosis of the aorta might produce hypertrophy of the left ventricle.

DR. FALK said that he had found that the arteriosclerosis produced by injections of adrenalin might be prevented or hindered by the simultaneous injection of other substances, such as bouillon cultures of staphylococcus aureus, oil of turpentine, aleuronat, iodipin, and oil of sesame. All these substances produced an increase of the leucocytes in the blood which very probably had an action antagonistic to the process leading to necrosis of the vessels. The necrotising effect of adrenalin was, on the other hand, very much increased by subcutaneous injections of substances such as croton oil and the toxin of staphylococci. A temporary increase of the blood-pressure was necessary as a predisposing or preparatory condition for the alterations of the vessels. Mechanically produced increase of the blood-pressure, together with the injection of other toxic substances, had the same effect as injections of adrenalin.

The Differential Diagnosis between Cardiac Hypertrophy and Pericardial Effusion.

Dr. WOLFFHÜGEL (Landshut) said that even small amounts of pericardial effusion and cardiac hypertrophy might be recognised by the occurrence of characteristic alterations of the position of the anterior borders of the lungs. The examination must be performed with the patient in the erect and in the horizontal positions successively. If in the erect position the lingula was displaced and the right border of the heart was found under the sternum and if in the horizontal position this border was found on the left side of the sternum and the internal border of the superior lobe of the left lung was displaced upwards and to the left a small pericardial effusion was present. If in the angle between the right border of the heart and the liver percussion gave a dull sound which disappeared in the horizontal position and if in this position the left border of the superior lobe was displaced upwards and outwards the diagnosis of pericarditis was absolutely certain and enlargement of the right ventricle was excluded.

Inadvisability of Gymnastic Exercises in Myocarditis.

Dr. WACHENFELD (Nauheim) spoke against the use of gymnastic exercises in myocarditis. He considered that such exercises were not only unnecessary but even mischievous and that gymnastics in every form, whether resistance exercises, or exercises in which mechanical apparatus or electricity was employed, ought to be avoided, especially when the metabolism in the muscular substance of the heart was reduced.

The Secretion of the Pancreas.

Dr. BICKEL (Berlin) said that the pancreatic secretion was dependent on nervous influences, which might either hinder or promote the flow. By offering food to hungry animals the secretion was increased but if the animals from any cause became angry it was hindered. Apart from dietetic considerations the secretion might be affected by drugs and mineral waters. Secretin, hydrochloric acid, pilocarpine, alcohol, tincture of cinchona, and solution of common salt had the effect of promoting the secretion, whilst atropine, morphine, opium, bicarbonate of sodium, sulphate of magnesium, sulphate of sodium, and most of the alkaline mineral waters hindered it. The secretion of the pancreas depended in some degree on the production of hydrochloric acid in the stomach, and if this latter function was interfered with the pancreas suffered also—a circumstance which must be considered in the treatment of the disorders of digestion.

Dr. ERNST MEYER (Halle) recommended for rectal feeding an enema of cream mixed with pancreatic juice, by which means a better absorption of the cream was obtained. An enema consisting of cream, peptone, and pancreatin had a high calorific value; it was easily prepared and did not irritate the intestine.

The Importance of Water for the Physiological Disintegration of Fat.

Dr. HEILNER (Munich) said that by experiments conducted in Voit's respiration chamber it had been proved that the administration of water to a hungry dog increased the physiological disintegration of fat by about 9 per cent. and also increased the nitrogen in the urine. These phenomena were absent when the water administered was required in the organism for some other definite physiological purpose. This was the case when, together with 150 grammes of water, 32 grammes of dextrose were given, so that the water was used to dissolve the latter; similarly when water was given to animals at a temperature of 33° C. in the chamber it served to replace the water lost by perspiration. The conditions were nearly the same for the physiological disintegration of albumin. From this it might be inferred that an abundant supply of water had a specific dynamic action on the katabolism of the living tissues.

The Digestion of Albumin in the Body.

Dr. LOMMEL (Jena) said that after a dog had received an intravenous injection of pig's serum the nitrogen appeared in its urine in the form of urea. Dogs, however, did not assimilate the albumin of an animal of their own species, and if such albumin was administered, even in great quantities, to hungry dogs the nitrogen of it did not appear in their urine in the form of urea. It had been found that graminivorous animals assimilated the serum of animals belonging to other species only after being immunised against it. Dogs, however, assimilated the serum of animals belonging to other species at once.

Chronic Poisoning by Manganese.

Professor JAKSCH (Prague) said that he had described in the year 1901 three cases of poisoning by manganese, the principal symptoms being convulsive laughing and crying, walking backwards, exaggeration of the reflexes, and symptoms of mental aberration. In 1902 a new case came under his observation in which, instead of the convulsive laughing and crying, the patient's face showed a mask-like expression. In 1907 a workman employed at the same factory from which the other cases had come presented himself. He was in a state of great mental excitement, walked backwards, and had the characteristic gait of manganese poisoning. Convulsive laughing and crying were absent. The visual field was greatly reduced. The patient recovered within 20 days under the use of high-frequency currents. Possibly the case was one of a functional neurosis—manganophobia. The toxic effects were produced by the manganous salts only.

Myasthenia Pseudoparalytica and Hyperleucocytosis.

Professor PEL (Amsterdam) mentioned the case of a woman, 38 years of age, who showed the symptoms of Erb's disease, including the characteristic physiognomy, ptosis, diplegia facialis, dysphagia, difficulty of utterance, myasthenic reaction, and attacks of dyspnœa, but no atrophy of the muscles. The cause of her illness was extreme physical over exertion, combined with mental depression. A remarkable feature of the case was that on the days when the patient felt dull and miserable there was an enormous increase of leucocytes in her blood, the number reaching 16,000 in a cubic millimetre, whereas on the days when she felt tolerably well there were only from 6000 to 7000 in a cubic millimetre. Professor Pel was of opinion that this leucocytosis was caused by chemotaxic poisons, which had also an unfavourable effect on the general state of the patient.

The Treatment of Aphasia.

Dr. GUTZMANN (Berlin) said that the results of the treatment of aphasia by systematic exercises even in elderly patients were generally good. Exercises should be begun when the aphasia had continued for three months or six months, provided that the general state of the patient was good and the intellect clear. Young persons, of course, gave better results, but patients between 40 and 50 years of age had been successfully treated. Neither the duration nor the intensity of the aphasia was a contra-indication against the exercises and Dr. Gutzmann mentioned a case in which he had successfully treated cortico-motoric aphasia of ten years' duration.

Neuroses of Military Men after a Campaign.

Dr. HONIGMANN (Wiesbaden) described under the name of "Kriegsneurosen" nervous troubles observed by him in Russian officers who had been wounded during the war with Japan. The symptoms were—like those observed in traumatic neurosis or the "railway brain" of civilians—partly of a neurasthenic and hysterical, and partly of a hypochondriacal character (hysterical monoplegia, hyperæsthesia, hypoæsthesia, and hemianæsthesia). In many cases the nervous troubles depended on physical alterations of the central nervous system although not on local affection of the brain. The treatment of these nervous troubles had generally a better result than in cases of traumatic neuroses after accidents in factories or workshops.

The Influence of Certain Drugs on the Temperature of the Living Body during Exposure to Heat.

Dr. WINTERNITZ and Professor VON MERING (Halle) said that they had examined the course of the body temperature during exposure in an electric light bath with and without the administration of antipyretics, such as phenacetin and salicylate of sodium. They had found that the temperature was the same in both events. It was therefore proved that on exposure to a high temperature the thermo-emissive power of the body was so adjusted that no further effect oduced by antipvretics. Injections of atropine and pine had no influence on the temperature, a fact proved that what influenced the temperature was not sible liquid perspiration but a certain degree of re of the skin which was not suppressed by atropine.

SOME TURKISH LAZARETS

OTHER SANITARY INSTITUTIONS IN THE NEAR EAST.

VII.[1]

THE CAMARAN LAZARET (*continued*).

of Communication.—Lack of Telegraphic Communica- n with the Mainland; New Cable since Laid Down.— e Telephone.—The Décauville Railway and Rolling- ck.—The Machinery Building and its Contents — neral Depôts; Coal Depôt.—Installation for Manu- turing Bricks, Tiles, Concrete Blocks, &c.—Proposals nnected with the Administration of the Lazaret.—The lue of the Indian Rupee.—Total Estimated Cost of the roposed New Works.—The Sanitary Control of Ships rrying Pilgrims to and from the Hedjaz.

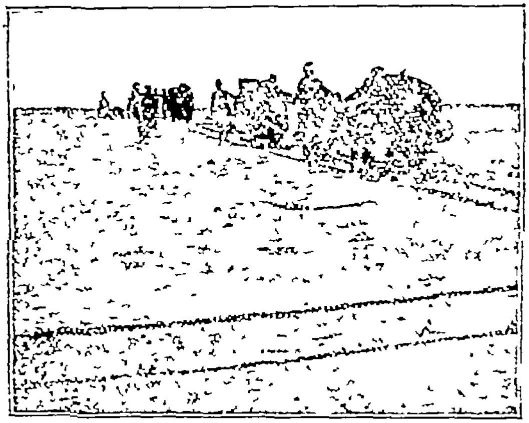
E successful working of a large institution like the ran lazaret must depend to a considerable extent on the nce of efficient and rapid means of communication— y, between the lazaret and the central controlling body onstantinople; and, secondly, between the different ons of the lazaret itself.

rmerly the island of Camaran was connected with the ian mainland by a telegraph wire. Telegrams from tantinople went by way of Perim to Sheikh Said (on the land opposite Perim) and thence to Hodeidah and aran. The cable crossing the straits from Ras-el-Bayadh e island was laid down in February, 1893. It seems to worked well for about five years, indifferently (requiring tant repair) for the next three years, and in 1902 topped working. In 1903 the cable was taken up found to be in a very bad condition; some incomplete irs were effected but a month later communication again interrupted and a little later still the cable removed altogether. At the time of the Commission's , to Camaran the island was quite cut off from the main- l and telegrams had to be sent to and from the latter by bouk. The delays were serious not only at that end of line but also, it would seem, elsewhere, and it sometimes : three, four, or five days for a telegram to pass between naran and Constantinople. The representations on this nt made by the Commission on its return have had sfactory results: the cable between the mainland and naran has been relaid and better arrangements have been le. The result is that telegraphic communication between lazaret officials and the central administration in Con- ntinople is now both much more certain and much more id than it was in the early part of the year, and the gain efficiency in the administration of the lazaret should be respondingly great.

For the purposes of internal communication between ferent parts of the lazaret itself there exists at present ly the Décauville railway. There was formerly a telephone stem connecting the central offices with the medical man's use in each cordon. It was put up in 1898, but for lack of lled attention it has ceased to work; indeed, the only aces of it left are a few of the receivers much spoilt by the imate. The Commission proposes to re-establish the lephone system connecting the central offices with each rdon, with the three disinfecting blocks, and with the spitals, and to put it in charge of a skilled employee who ll be responsible for its proper working and upkeep.

The railway is a Décauville line, of 60 centimetres (about feet) gauge. It has been in use for some nine or ten ears and has suffered considerably from the action of e climate and of the salt and often damp sand on which it is laid. Much of it is to be relaid, and two kilometres of new lines have been bought and are being gradually put down in place of the old. The new lines weigh nine kilogrammes the metre, the old ones only five; it will thus be possible to run a small engine on the new line if desired, an improvement that it was impossible to introduce on the existing one. A large new building is also being put up to shelter the rolling stock in place of the poor arish sheds hitherto employed for this purpose. The rolling-stock consists of 17 coal-trucks (two capable of holding half a ton, and the other 15 of one ton capacity each); 42 trucks for carrying the pilgrims' luggage (some of them are seen in Fig. 26); 11 tanks for sewage removal (as described in Article V.); one pump on wheels for use at the cesspools; two carriages for the use of the *personnel*, one of six places and the other of three; and four water-cisterns. In addition there is the moveable disinfecting stove mentioned in Article III.; and a crane mounted on a truck, the wheels of which are, however, too wide apart to run on the existing line. At present manual labour is employed to push these various objects along the line; the question of the purchase of a locomotive is adjourned for the present. With the disappearance of the existing system of excreta disposal and the reduction of the whole length of the lazaret by about one half the length of the railway will be very greatly diminished. Its plan also will of necessity be somewhat modified, with the modification of the general plan of the lazaret, as described in earlier articles. Branches will run from the head of each landing jetty to the disinfecting blocks; the main line will connect the latter with the cordons, and these with the central administrative buildings; and other branches will run to the hospitals, the Mervani jetty, and other outlying portions of the lazaret.

FIG. 26.



The Décauville railway; trucks with pilgrims' luggage.

The remaining buildings of this lazaret do not require any lengthened description. The large stone structure known as the "machinery building" stands on a cliff close to the northern shores of the Camaran Bay. It contains the distilling apparatus, the ice machine, the pump for raising sea water, and the generators and motors for working these machines. In an annexe is the forge; and there are several other rooms, two of which are occupied by the head engineer, and one is a workshop containing drills, circular saws, lathes, and other instruments, all of which are worked by steam. These various machines are of the greatest use in the repair and upkeep of the distilling and ice apparatus, the railway, the stores, and the many other installations of the lazaret.

There are several large store-rooms (*magasins*) in the lazaret. One occupies the ground floor of the residency described in Article VI. Another is a large stone building, with iron roof, on the Mervani plain. An almost identical building is used for a coal-store; it is situated close to the Mervani jetty; it can hold as much as 500 tons of coal and a branch of the Décauville railway enters it at one end and leaves it at the other. There are also several arishes used as stores.

Finally, the only group of structures that need further mention are those connected with the manufacture of various building materials employed in the original construction and in the upkeep of the lazaret. When the "refection" of this lazaret was undertaken some ten years ago a series of costly machines was installed on the island with the object of preparing on the spot the bricks, tiles for roofing, floor-tiles, concrete blocks, and other materials required for the new buildings. Most of these machines still exist, though they are now rarely, if ever, employed. The bricks manufactured on the island never proved very satisfactory, and as an excellent building stone is found in practically unlimited quantities on the island itself and on the adjoining mainland the Commission recommends that in future all "pucca" buildings shall be constructed of stone. A considerable stock of unused bricks exists in this portion of the lazaret; many of them are of bad quality but the good ones can be employed for inner walls in the new buildings that it is proposed to put up. In the climate of Camaran bricks do not seem to do well for outer walls; when so employed it has always been deemed necessary to cover them with a thick coating of lime plaster, as they crumble away if exposed to the air. But (as shown in several of the illustrations that have appeared in earlier articles) the plaster tends to fall off, leaving the bricks exposed all the same. In some buildings, notably in many of the latrines in the cordons, the outer coat of plaster has completely disappeared and the brick walls are crumbling to pieces. In other buildings, where better bricks and perhaps better plaster have been used, the condition is less marked. The falling of the plaster is further contributed to by the absence of a damp proof course in any of the buildings. This expedient of preventing damp in outside walls seems to be quite unknown in this country. The tiles for roofing and flooring and the concrete blocks (for the jetties, &c.) manufactured at Camaran have given rather better results than the bricks.

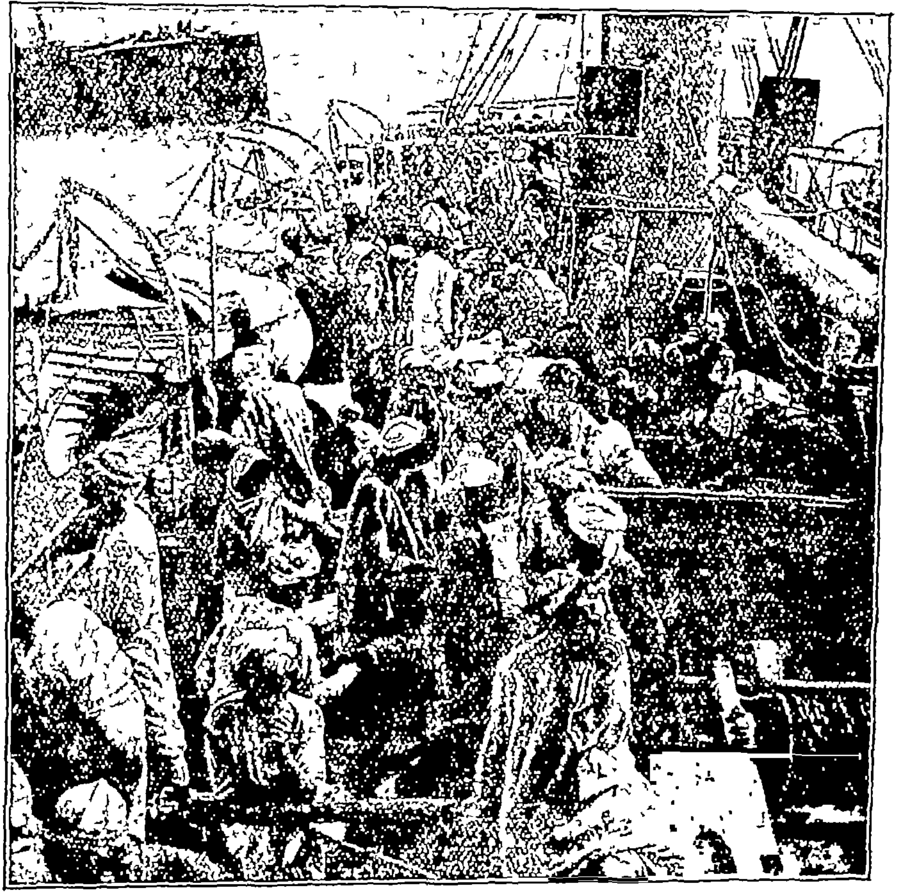
---

[1] Nos I., II., III., IV., V., and VI. were published in THE LANCET of pril 27th (p. 1165), May 4th (p. 1251), 11th (p. 1317), and 18th) 1309), and June 1st (p. 1515), and 8th (p. 1607), 1907, respectively.

This completes the description of the principal buildings and installations of the lazaret of Camaran. The Commission's report deals, however, not only with the buildings and installations and proposals for their improvement and completion, but also with a large number of questions of various kinds connected with the administration of the lazaret. Several modifications are proposed in the *personnel* of the institution, the most important of which are the nomination of an assistant director, the assigning of definite responsibility to individual employees for the upkeep of the various buildings and installations, and the formation of squads of trained labourers to be placed under the orders of those employees. The lazaret as a whole has hitherto suffered considerably from insufficient attention to the upkeep and repair of the buildings of which it is composed; the Commission lays great stress on this point and makes a series of recommendations for remedying the defect in future. Among other things it advises placing at the disposal of the director a sum of P.3000 (£T.30) a month for urgently needed repairs and purchase of materials, a sum which he will be at liberty to spend without asking the preliminary consent of the Constantinople Board of Health (which often causes delay) and on the sole condition of accounting satisfactorily for its expenditure at the end of the month.

Another valuable result of the Commission's labours has been in connexion with the rate of exchange of the Indian rupee when taken in sanitary dues at Camaran or Jeddah. Hitherto that coin has been taken at the value of only 5½ piastres (11*d.*), whereas its real value is 16*d.*, or 8 piastres. Its exchange value with the local sarafs, or money-changers, varies between 7 and 7¾ piastres. Its being taken at the low rate of 5½ piastres by the sanitary authorities caused a very serious loss to Indian pilgrims (who are called upon to pay over 70 piastres for ten days' quarantine). Moreover, the marked difference in the two local values of the rupee led to no little speculation and abuse. This will now be

FIG. 27.



Deck of a pilgrim steamer approaching Yanbo.

done away with, as the Board has decided to take the rupee for quarantine dues at 20 paras (*1d.*) less than the local rate of the day with the money-changers. It will henceforth, therefore, be taken at from 6½ to 7¼ piastres, instead of 5½ as hitherto.

Estimates of the cost of each new work proposed are added in the Commission's report. It will suffice here to mention the total sum, which is placed at £T33,000, or £30,000 sterling. Detailed recommendations are also made as to the best method of carrying out the new works. It should further be added that the majority of the proposals made by the Commission have been approved and adopted by the Board of Health and that several of the more urgently needed works (involving an outlay of some £3000) are to be put in hand at once. For the other more costly works new credits will have to be obtained and this must necessarily involve a certain amount of delay.

In this and the preceding articles I have dealt at considerable length with the great lazaret of Camaran. It is in that lazaret that the large majority of pilgrims coming to the Hedjaz from beyond the Straits of Bab-el-Mandeb undergo a period of quarantine together with the other measures described in an earlier article. During that period the ships which take them to the island are thoroughly cleansed and disinfected, and the crews are landed and undergo a douche-bath, while their clothes pass through the disinfecting stove. At the expiry of the quarantine period the pilgrims are once more put on board sambouks and sail or are towed back to their now clean and disinfected steamers. From Camaran the steamers proceed directly to Jeddah; the voyage lasts about 48 hours. A few words may be said here as to the sanitary control of the pilgrim ships themselves.

The sanitary condition of the pilgrims during their voyage to the Hedjaz ports is mainly regulated by a code of rules known as the "*Règlement spécial* applicable au Pèlerinage du Hedjaz," which is annually revised by the Constantinople Board of Health. Ships sailing from Indian ports, which form a considerable majority of all pilgrim ships from the south, come under a set of regulations issued by the various Indian Governments under the title of "General Instructions for Pilgrims to the Hedjaz," which are based mainly on two Acts, the Pilgrim Ships Act of 1895 and the Bombay Protection of Pilgrims' Act of 1887. These various codes of regulations correspond very closely in their main provisions with the rules embodied in successive international sanitary conventions, and codified in the last convention, that of Paris, 1903. These rules deal with such questions as the amount of space allotted to the pilgrims between decks (in most instances 16 square feet per pilgrim); the provision of latrine accommodation, of water-supply, of hospital beds, of a distilling apparatus and a disinfecting stove, questions concerning the fitness of the ship to go to sea, the presence of fire-extinguishing apparatus on board, and many other similar questions.

A considerable number of pilgrim ships contravene one or more of these rules each year, but it is satisfactory to note that the Indian Acts and regulations are very strictly enforced and that the ships taking pilgrims from Indian ports—as also those from Further Indian ports—are among the cleanest and most sanitary of all steamers going to the Hedjaz. *Fig.* 27 shows the deck of a small pilgrim steamer of some 450 tons; it was the steamer by which I travelled from Jeddah to Yanbo and the photograph was taken at the moment of arriving at the latter port.

(*To be continued.*)

MANCHESTER.

(FROM OUR OWN CORRESPONDENT.)

Schools for the Feeble-minded.

AMIDST the clamour and the clangour of the controversies raging round and about the education question it is cheering to turn to the good work done in Manchester to help those whose mental feebleness calls for sympathy and whose future should give thought to those anxious to avert the mental and physical degeneracy that threatens a large section of the nation. The fourth annual report by Dr. H. Ashby, who has from the first given most valuable help to the scheme, addressed to the Manchester education committee, gives some valuable and interesting information as to the schools for the feeble-minded and for cripples. There are three of these special day-schools in Manchester, in one of which there are at present 90 children and in the two others 80 and 95 respectively. In addition to these 40 mentally defective children are inmates of the Sandlebridge boarding schools belonging to the Incorporated Lancashire and Cheshire Society for the Permanent Care of the Feeble-minded and 43 suffering from epilepsy are at the Manchester David Lewis Epileptic Colony School, near Alderley Edge. There is also at Swinton House a residential school for the physically defective in which the accommodation was increased during 1906 from 30 to 60 beds. At the close of 1906 at the three schools for the mentally defective there were 238 in attendance, 159 boys and 79 girls. Dr. Ashby pays a warm tribute to the teachers in these schools, and it may well be imagined what "enthusiasm and interest" must be required in this special work. If these qualities are absent the more than usual trials and discouragements must be almost heart-breaking, but Dr. Ashby says that "the teachers have interested themselves not only in the education of the children but in every phase of their lives, whether at school or at home." It was at first difficult to persuade parents to send their children to a special school but that difficulty is lessening and the time is looked forward to when parents will recognise the value of these schools. But there is a class of children lower in mental power than those for whom these schools are doing such good work; and the question is asked, What must be done with these? They do not benefit or gain lasting advantage by attendance at a day-school. They come up for examination in considerable numbers, most of them have to be rejected but some are admitted in hope of their improvement, but it generally turns out that even these have to be discharged. It seems hard to refuse admission or to discharge them afterwards, but Dr. Ashby's experience is that "the lower class defective learns nothing, or next to nothing, of the value of figures or words, even after a year or more of teaching, and time given to them, in these respects at least, is largely thrown away." But he remarks that they improve in conduct and behaviour and some of them in manual work. In his opinion the only solution of the question is "in the establishment of residential institutions, where the education and training would be purely manual, where the inmates by their work would make some slight contribution towards their maintenance." Without such care these children, as he says, are certain to "drift into the workhouse or recruit the criminal or chronic inebriate class." These degenerates, moreover, reproduce their kind which should be prevented, so that it becomes a matter of urgency to care for them during their whole lives. Dr. Ashby speaks encouragingly of the brighter children who in the course of time have learned to read an infant primer fluently, to add and to subtract sums of money, and to write a fairly good hand. But with them also the greatest advance has been in manual work, their drawing, moulding, woodwork, and knitting being "most creditable." As regards their future, "the great thing to recognise is their capacity for manual work under supervision." Dr. Ashby advocates the teaching of the simpler handicrafts by practical men to boys of from 14 to 16, and "domestic economy" to girls. This seems the most hopeful direction to take with these unfortunate derelicts. Last summer 80 of the children spent a happy fortnight at the country school at Mobberley, with much enjoyment and to their great benefit, and the experiment will be repeated this year. At the Swinton School for Cripples there were 63 inmates in all during the year. For the most part they were of average mental ability but backward from having had little or no systematic instruction. The greater number suffered from spinal or hip disease. Some few leave sufficiently well to go to work; some become too ill to learn, while others have to go to hospital, and if sufficiently recovered return to school. Very little medicine and no alcoholic beverages have been taken, while the food is plain and plentiful. Much more might be said of the efforts made to brighten the lot and to improve the prospects of these poor children, but the schools show what a wide field exists for the exercise of a sane philanthropy that will not only cheer the sufferers but will bring back in return many advantages to the country.

Street Accidents.

Three children were killed in Manchester the other day, and at the inquests held on June 17th it came out that the manner of their deaths was a very common one. The first, aged 16 months, was playing on the doorstep, but went to the roadway where he was knocked down by a lorry, run over, and killed. The second, aged three years, was playing on the footpath with her brother, when she ran in front of a post-office mail van, was run over, and died while being taken to the infirmary. The third, aged one year and nine months, was playing in the street and was knocked down by a lorry and killed. In none of the cases was the driver held to be blameable, and the coroner said it was not fair to them that parents should allow their children to play in the streets. But what are the parents in the "mean streets" to do? There are no playgrounds near to which the children may be taken. The mother, either from necessity or mismanagement, has, in many cases, to leave to others the care of her children while she is working. The obvious solution would be to provide more open spaces in poor neighbourhoods where the children would be safe, and perhaps to make it a punishable offence for parents or caretakers to allow these little children to play in the streets.

Old Rum Casks.

A rather unusual death from "misadventure," according to the verdict, occurred just lately. A Bury dyeing company bought some old rum puncheons which were left out of doors and the rain got into them. On the next day the man in charge drew off the liquid and took it home and at night he and some friends drank it in his greenhouse. All were affected by it and one became unconscious, was taken home on a wheelbarrow, and died about midnight. At the inquest a medical man attributed the death to acute alcoholism. The rum, as it must be called, was said to be between 28 and 30 points overproof. Old rum casks seem to retain for a long time their evil potency.

On Children's Processions and Excursions.

In an address given recently in Manchester Dr. A. C. Magian made some judicious remarks on the processions of children, that are supposed to be enjoyable and enjoyed, during Whitsun week. Whatever the weather may be they assemble in their thousands in Albert-square and afterwards walk through some of the principal streets. There is what looks almost like rivalry as to which of the religious bodies can show the greatest number, but it is judiciously arranged that members of the various bodies shall not walk on the same day. The same objections apply with even greater force to the long railway excursions it is now common for the schools to make at Whitsuntide. Those who have seen the poor little things, dressed often in the flimsiest clothes and with poor thin shoes, tired, wet, and cold, if the day should be damp or if it rains, as it not infrequently does in the neighbourhood of Manchester, will readily believe Dr. Magian's statement that he knew for a fact that hundreds of children had caught colds, if nothing worse, during Whitsun week and he was certain that many of these would develop pneumonia and other serious diseases. There is no doubt that the children look forward to these processions and excursions and invest them with all the delightful anticipations that the child mind can picture, but the anticipated pleasure turns out in very many cases to be a painful experience.

June 18th.

LIVERPOOL.

(FROM OUR OWN CORRESPONDENT.)

The Treatment of Epilepsy: Work of the Home for Epileptics at Maghull.

THE annual meeting in connexion with the home for epileptics at Maghull was held on June 15th, when a large party of ladies and gentlemen were afforded an opportunity of visiting the institution and seeing for themselves the excellent work which is being carried on in the treatment of epilepsy. The Lord Mayor of Liverpool presided. Mr. J. R. Paton, who was unable to be present, sent a cheque for £100. The eighteenth annual report stated that 19 males and 17 females had been admitted during the year, the total number in the home on Dec. 31st, 1906, being 209, classified as follows: First class patients, five; second class, 52; intermediate class, four; and third class, 148. The usual kinds of work had been followed, that for the men being outdoor work in the fields and gardens whenever their physical condition allowed. Such men as were not physically equal to the hard work and exposure to weather which agricultural work called for were engaged indoors or under cover at joinery, &c., or as porters or messengers between the homes. The women, too, were engaged when possible in gardening, but for the most part the domestic work of the home, the laundry, the kitchen, and duties arising out of these fully occupied their attention. Hardly any of the patients had any knowledge of agricultural work before going to the home, but after a course of training and under effective supervision they were shown to be capable of doing satisfactory work. The farm supplied the home during the year with all the milk and vegetables required, as well as with a certain amount of bacon, eggs, and poultry, the total value of the food thus furnished for its own use being £690 and the outside sales £632. The farm account, unfortunately, showed a loss this year. The plan of making a small weekly allowance to those workers who had acquired some skill and did their work steadily proved advantageous, and gave a much-needed stimulus to the patients, who were without the motives urging to steady and continuous effort which act as an incentive in ordinary life. In the day school the young patients were taught "the three R's," kindergarten, light basket-work, &c. The children had also made collections of wild flowers and had learnt the names, and showed interest in their small gardens. In the evening continuation classes during the winter months there were about 153 adults on the register and the attendance and conduct were very good. The receipts from patients showed a considerable falling off, owing to the temporary reduction in the number of the first-class patients; but, on the other hand, economies had been effected and the maintenance account had worked out satisfactorily. The committee had now felt compelled to consider the question of making further provision for children, and it had been decided to erect a home to accommodate 30 boys and 30 girls at an estimated cost, including furniture, of £8000. Sir James Crichton-Browne, who was especially invited, addressed the meeting and said that the Maghull home was the first institution established for epileptics in this country, and, therefore, the pioneer in a work that was still greatly in need of extension, and he was present to show his appreciation of the admirable methods pursued in it. His impression was that epilepsy was increasing; the modern modes of life were more and more conducive to the instability of the brain and the higher nerve centres out of which epilepsy sprang. Already they were in possession of remedies which materially reduced that instability and explosiveness of the brain which gripped them. He particularly rejoiced to find in that home a medical staff who were animated by the true scientific spirit and took no despairing view of the evil with which they had to cope. Dr. William Alexander was satisfied by clinical and pathological observations that epilepsy was a curable disease and he quite agreed with him. It seemed to him that Dr. Alexander was on the right track, and should he succeed then the Maghull home would have conferred inestimable blessings on suffering humanity. Among the other visitors were Sir Edward and Lady Russell, the rector of Liverpool (Canon Kempthorne), Dr. William Carter, and Dr. J. M. Rhodes (Didsbury).

June 18th.

WALES AND WESTERN COUNTIES NOTES.

(FROM OUR OWN CORRESPONDENTS.)

The Midwives Act in Cardiff.

THE Midwives Act is administered in Cardiff by the health committee of the city corporation with the medical officer of health, Dr. E. Walford, as executive officer. A woman inspector, who is a certificated midwife and is on the staff of the sanitary department, visits the residences of the registered midwives in the district and supervises their practice. During 1906 she found that among the 117 midwives on the register 85 had provided themselves with a case book, record book, washable dresses, a bag, and appliances. Of the remainder all but seven had case books and all but 11 had record books. 20 did not have washable dresses, bags, or appliances and four had not provided themselves with any of the articles required by the regulations of the Central Midwives Board. A course of training for midwives has been established by the University College of South Wales and Monmouthshire, instruction being given by Dr. Ewan J. Maclean, lecturer on midwifery to the College. During 1906 the course was attended by 39 pupil midwives from Cardiff and 50 from elsewhere. Practical training is also given in the maternity department of the Queen's Nursing Institute.

The Temple Memorial Home for Inebriates.

A home for male inebriates, which has been established by the Church of England Temperance Society at Cinderford in the Forest of Dean, was formally opened by the Bishop of Gloucester on June 11th. The house and surrounding grounds of 27 acres were purchased from the Crown. The total expenditure, including furnishing and alterations, has been about £5000, a sum which has been raised by voluntary subscriptions. The institution, which is intended to be a memorial to the late Archbishop of Canterbury, will replace a somewhat smaller home which has been established about seven years at Battle in Sussex. There is accommodation at Cinderford for 55 men, some of whom pay a weekly sum of 25*s.* and others 10*s.* 6*d.* There will be a domestic staff of seven persons, of whom five are men. As far as practicable employment will be found for the inmates. The report of the home at Battle for the year 1906 shows that during that period the institution was nearly self-supporting; indeed, if the patients had paid an additional 5 per cent. it would have been quite self-supporting. Of the 46 patients who left the home in 1906 it is said that 14 had been heard from and were believed to be doing well. The average time of stay in the home was nine months. The Cinderford house is now the only home for men which is administered by the Church of England Temperance Society, but the society has homes for inebriate women in different parts of the country, one being situated in Norfolk, one in Torquay, one at Herne Hill, and a fourth near Birmingham. The results at all these institutions are considered to be satisfactory.

An Action for the Recovery of Medical Fees.

In Camelford county court on June 13th Mr. E. J. Jerome of Camelford sued a lady for £43 for medical attendance on her brother. Evidence showed that the defendant had written and asked Mr. Jerome to attend her brother and that her solicitor had sent him sums of money on account. For the defence it was urged that the defendant was not responsible and that the charges were excessive; £25 had been offered in settlement but this the plaintiff had refused. His honour gave judgment for the full amount with costs, remarking that as the defendant had asked Mr. Jerome to attend her brother he was justified in looking to her for payment.

June 18th.

SCOTLAND.

(FROM OUR OWN CORRESPONDENTS.)

Changes on the Staff of the Royal Infirmary, Edinburgh.

OWING to two members of the honorary staff—namely, Dr. Alexander James, senior ordinary physician, and Dr. C. W. MacGillivray, senior ordinary surgeon—having completed their term of office the managers have promoted Dr. William Russell, senior assistant physician, and Dr. J. W. B. Hodsdon, senior assistant surgeon, to fill the vacancies thus formed. Vacancies have thus been made for a new assistant physician and a new assistant surgeon. The candidates for the assistant physiciancy are Dr. Edwin Bramwell, Dr. W. T. Ritchie, Dr. D. Chalmers Watson, Dr. Edwin Matthew, Dr. J. D. Comrie, and Dr. J. Eason; and for the assistant surgeoncy Dr. J. W. Struthers, Dn. H. Wade, and Dr. W. J. Stuart. These posts are to be filled up this month but all the appointments mentioned date from Sept. 1st next.

Presentation to Miss Spencer.

At a meeting of managers of the Edinburgh Royal Infirmary held on June 10th, Miss Spencer, on her retirement from the post of lady superintendent, was presented by the members of the board with a silver tea service and tray "as a token of their high appreciation of her most efficient, valuable, and devoted services to the institution during 30 years, first as assistant lady superintendent and then for the past 20 years as lady superintendent of nurses."

The Health Report of Edinburgh for 1906.

This report has just been issued by the medical officer of health, Sir Henry D. Littlejohn. It contains some interesting statistics. The death-rate was 14·26 per 1000, practically the same as in 1905. The highest mortality was in the fourth week of November and the first week of April. The birth-rate was 22·41 per 1000; in 1901 it was 24·99; in 1891, 28·25; in 1881, 32·23; and in 1871, 34·89. Of the total deaths amounting to 4868, 862 were of infants under one year of age. As regards causes of death, tuberculous disease caused 591 deaths, as compared with 640 and 654 in the two preceding years; pneumonia caused 482 deaths and cancer 330; the deaths from the zymotic diseases were 258, as compared with 328 in 1905 and 690 in 1897. No deaths occurred from small-pox. The notifications of infectious diseases numbered 2147. The report is altogether one with which the city and its health officer may well be satisfied.

Complimentary Dinner to Dr. J. M. Beattie.

Dr. J. M. Beattie, who has for a number of years been senior assistant in the pathological department and also lecturer in bacteriology in the University of Edinburgh, was entertained to dinner by a large number of his friends as an expression of goodwill on the eve of his leaving Edinburgh to take up the duties of professor of pathology in Sheffield. Dr. P. A. Young occupied the chair in virtue of his being president of the Australasian Club. The toast of the evening was proposed by Professor W. S. Greenfield who spoke in highly appreciative and affectionate terms of Dr. Beattie. Sheffield is to be congratulated on the selection of Dr. Beattie who, while an accomplished pathologist, is also a most pleasant and affable colleague.

Glasgow Ear, Throat, and Nose Hospital.

The annual meeting of the subscribers to this hospital was held recently. Dr. Thomas Barr submitted the medical report which stated that an average of 46 patients were seen by the medical staff every day on which the hospital was open during the past year. An average of ten new patients was dealt with daily, or a total of 2806. In the treatment of these patients 533 operations were performed under a general anæsthetic. It is noteworthy that 1000 out of the 2806 new cases coming for treatment were children under 15 years of age. In connexion with the university course of lectures 58 students received practical instruction. The financial report showed an income of £785 and an expenditure of £1003, leaving a debit balance of £218.

The Glasgow Dental Hospital.

The annual report of this hospital shows that during last year the number of cases treated was 7728. As the hospital is only open for two hours on five nights of the week this gives an average of 28 cases each night. Of the total operations, the largest proportion were of a conservative character, there being 2665 extractions and 4206 conservative operations. The gratifying feature of the year's work was the increase in the number of students at the Dental School On Dec. 31st, 1906, there were 35 students on the roll, as compared with 27 at the close of 1905. In connexion with the finances of the hospital it seems surprising that only £70 were subscribed last year by the general public for the upkeep of the hospital, while of that sum only £2 were contributed by the working classes who benefit most largely by the institution. At the general meeting it was determined to appeal to the public more widely for funds on the ground that if the University were to be approached to grant a degree in dentistry they would require a more modern and fully equipped institution.

Sanitary Condition of Lower Renfrewshire.

In a report just issued for Lower Renfrewshire stress is laid upon the fact that during the last year there was an abnormal increase in the cases of infectious disease, the number of cases visited being 661 more than in the preceding year. While this remarkable increase was principally due to epidemic outbreaks of measles in almost every village in the district, there was also a decided increase in all the diseases with the exception of enteric fever, which has been gradually decreasing year by year until it has now almost reached the vanishing point.

Dunoon Convalescent Homes.

The new wing of the West of Scotland Convalescent Seaside Homes at Dunoon was opened on Saturday last by His Grace the Duke of Argyll. Designed in harmony with the rest of the buildings the block consists of a large number of bedrooms, directors' and medical officers' rooms, and apartments for the superintendent and the matron. Accommodation is now provided for 308 beds, the institution being one of the largest of its kind in the country. No fewer than 110,357 persons have received the benefits of the homes since they were instituted in 1869. The ordinary expenditure of the homes for the last three years has been £6500 and this will be materially increased by the extended accommodation now available. It is gratifying to observe that last year £3766 were subscribed by those connected with works, warehouses, &c.

St. Andrew's Ambulance Association (Aberdeen Centre).

At a meeting of the committee of this association it was reported that during the past year 13 classes had been held and that the number of pupils who had passed the examinations was 249. Colonel Douglass Duncan was reappointed chairman, Professor D. W. Finlay vice-chairman, and the Rev. Jas. Smith representative in the council of the association. The following were appointed examiners for the ensuing year:—Dr. William F. Croll, Dr. T. Fraser, Dr. Peter Howie, Dr. John Innes, Dr. Francis Kelly, Dr. W. R. Pirie, Dr. Alexander Ogston, Dr. J. Smart, and Dr. J. A. Watt, all in Aberdeen; Dr. Donald Campbell, Elgin; Dr. P. C. Garson, Huntly; and Dr. Duncan D. Mackintosh, Aboyne.

Aberdeen Public Health Matters.

At the last meeting of the public health committee of the Aberdeen town council a circular was submitted from the Home Office requesting the medical officer of health to supply certain information with reference to industrial employment. The medical officer reported that the death-rate for May was 13·15 per 1000, while the average death-rate for the same month for the last ten years was 17·4 per 1000. A subcommittee was appointed to make the necessary arrangements for the forthcoming congress of the Sanitary Association of Scotland to be held in Aberdeen in September next. This subcommittee met subsequently and arranged the programme for the congress. On Sept. 4th business will begin in the town hall, to be followed by a lecture delivered by some eminent member of the association. Lord Provost Sir Alex. Lyon will formally welcome the delegates on the morning of Sept. 5th and later the President will deliver his address. The visitors will then be entertained to a garden party or a drive by the corporation. The official dinner of the association will be held on the same evening. On Sept. 6th the delegates will, on the invitation of the town council, visit some of the public institutions in the city and in the evening the corporation will hold a reception. On Sept. 7th the visitors will in all probability visit Deeside or Donside.

June 18th.

IRELAND.

(FROM OUR OWN CORRESPONDENTS.)

Royal Sanitary Institute.

THE work of the Conference on Sanitation and Public Health, to be held in Trinity College, Dublin, from June 25th to 29th, will be divided into three sections—viz.: (1) Sanitary Science and Preventive Medicine; (2) Engineering and Architecture; and (3) Physics, Chemistry, Biology, and Meteorology. A reception-room will be opened at the Institution of Civil Engineers of Ireland, 35, Dawson-street, Dublin, on June 25th, at noon, and on the following days at 9 A.M., for the issue of all tickets in connexion with the Conference. The inaugural address of the President will be given in the Examination Hall, Trinity College, and the sectional meetings and conferences will be held in Trinity College. To those not connected with the Institute the price of the Conference tickets is 10*s.* 6*d.* each. These tickets may be obtained at the offices of the Institute, 72, Margaret-street, London, W., or at the local offices, 63, Dawson-street, Dublin.

Health of Belfast.

At a meeting of the public health committee of Belfast held on June 15th it was reported that for the week ended June 8th there had been 13 cases of cerebro-spinal meningitis, as against 22 in the previous week. Of the 118 patients at present in Purdysburn Hospital 36 are suffering from cerebro-spinal meningitis and eight deaths occurred during the week from that disease. It is satisfactory to know that cerebro-spinal meningitis is at last showing signs of abating in Belfast. The general feeling in medical circles is that the epidemic has gradually worn itself out, but it is doubtful whether the elaborate disinfection or the isolation of the patients has been a factor in the problem; it is just as probable that the warm weather may have something to do with the gradual dying of the meningococcus or of its becoming less virulent, but so far there is no experimental evidence from the laboratory confirming this. It is curious that in Belfast for the week ended June 8th, while there is a diminution in the cases of cerebro-spinal meningitis notified (13 as compared with 22 in the previous week), on the other hand, typhoid fever has increased from three to 11 cases.

Tuberculosis in Belfast.

The medical superintendent officer of health has in a report to the public health committee recommended it to take into consideration the advisability of inviting all the medical practitioners in Belfast to coöperate in the voluntary notification of tuberculosis and that they should be paid the ordinary fee which is paid for other infectious diseases. He has also recommended the appointment of two health visitors. At a special meeting of the city corporation held on June 17th a report from the public health committee was submitted that in consideration of the authorities of the Forster Green Hospital for Consumption reserving 25 beds for patients, nominated by the committee and approved as suitable by the medical superintendent of the hospital, the corporation should be recommended to pay the sum of 35*s.* per bed per week, the corporation to be represented on the board of governors by the Lord Mayor for the time being and the chairman of the public health committee for the time being, or, in case of their inability to act, by any two members of that committee nominated by the committee. The governors of the hospital undertaking that in the event of there being any vacant beds in the hospital over and above the number referred to, patients nominated by the public health committee will be admitted on payment of 20*s.* each per week, the agreement to hold good for a period of ten years. In other words, the city council will contribute to the consumption hospital £2270 a year for the ten years for the privilege of having 25 beds at its disposal. The 25 beds are to be additional to the present accommodation at the hospital. The hospital authorities will create further accommodation for the patients to the extent of their undertaking with the corporation. The plans for the extensions are ready and the work will be proceeded with whenever the agreement is completed. A motion to approve of the above arrangement having been proposed and seconded, an amendment was submitted to refer it to the public health committee and that the latter be instructed to take into consideration the immediate establishment of a municipal consumption hospital at a maximum cost of £12,500 for lands, building, and equipment. The amendment on being put to the vote was lost by 26 to 5. A subsequent amendment that no arrangement such as was given in the suggested plan should be entered into for a longer period than 12 months was defeated by 20 to 6 votes. The original motion was then put to the meeting and was carried.

Epidemic of Typhus Fever in Newry.

It has been decided to open the Canal-street Baths in Newry as an isolation hospital for typhus fever, and already five cases have been located in them—all children. On June 17th two fresh cases from a part of the town where nearly all the cases occurred were admitted to the workhouse fever hospital.

June 18th.

PARIS.

(FROM OUR OWN CORRESPONDENT.)

The French Income-tax and the Medical Profession.

THE Bill to impose an income-tax has excited the opposition of all the medical men of France. The point at issue is the stipulation made in one of the articles of the project. This states that the tax shall be estimated according to the net profits realised during the preceding year. As, however, no allowance is made for the expenses incurred in the exercise of the medical profession, though such allowance is made in regard to trade and industry, it follows that all fees will be considered as net income. The cost of instruments, of books, and of surgical dressings will not be deducted from the general income or profits. The tax will be levied on all; even the small fee granted by the authorities to the medical attendants of the poor for rendering gratuitous medical assistance to the indigent or to children assisted by the State or the commune, and the allowance made to hospital staffs, or the reduced payments received from benefit and friendly societies, &c. For going some distance in the country the sum paid will be taxed without any deduction being made for the cost of a conveyance. The payment for a licence to practise will not be suppressed. The tax collector will have the right to verify the accounts and to ask questions as to the persons who paid the fees; professional secrecy will be violated. The tax collector will always be able to assert that it was only to deceive him that the country practitioner professed to receive less for performing the same operation than the high fee paid to a celebrated surgeon who came expressly from a large town. The practitioner will no longer be at liberty to accept smaller fees from needy persons. Finally, it may happen that some of the fees are not paid but the tax-collector may refuse to believe it. The members of the profession are naturally alarmed by all these threats and from all sides protest loudly. The most important of these protests has been made at the Union of the Medical Practitioners of the Department of the Seine by Dr. Renon who read to this union a report which contained much evidence and information and which also recapitulated the complaints that had already been made. He insisted especially on the protestation adopted by the recent congress of practitioners which was composed of 1400 medical men and more than 100 medical societies, and some of these latter have more than 1000 members. This congress adopted a motion urging all its members to vote against the project. Dr. Renon, therefore, terminated his report by proposing that the administrative council of the Union of the Medical Practitioners of the Department of the Seine should adopt the following motion:—

> That widespread efforts should be made to enlighten public opinion on the dangers to which patients are exposed by the present project. That during the discussion of this project the members of the Parliamentary medical group should struggle energetically against the Bill, endeavour to obtain the maintenance of the actual state of affairs, but with some ameliorations in regard to the licence to practise; and, in the event of the Bill being carried must insist that the cost of the working expenses shall be deducted from the receipts made by medical practitioners, and the remaining net income only rendered susceptible to income-tax.

Juvenile Tabes with Ocular Complications.

At a meeting of the Ophthalmological Society held on June 4th M. Cantonnet showed a boy, aged 15 years, who was suffering from scoliosis and hereditary syphilis. When 13 years of age he began to have incontinence of urine. Eight months ago he developed oculo-motor paralysis of the left eye, which condition was much benefited by mercurial treatment. Lightning pains appeared five months ago. He now has diplopia, ataxia of the ocular muscles, inequality of the pupils with the Argyll-Robertson sign, and diminished sensation in the left side of the face. The patellar and tendo Achillis reflexes are absent. He shows neither Romberg's sign nor any locomotor ataxy.

Sulphur Waters and Mercurial Treatment.

M. Desmoullières and M. Chatin communicated to the Academy of Medicine at a meeting held on June 3rd the result of some investigations undertaken by them to determine the reason why at sulphur water health stations syphilitic patients could take mercury in doses which were four or five times larger than they could take in usual circumstances. Their investigations showed that sulphur waters act, not by the formation of an insoluble sulphate of mercury, but by augmenting the solvent power of the blood serum for albuminates of mercury. Sulphur waters, therefore, make it possible to give large doses of mercury without danger of mercurial poisoning. Moreover, if there be any accumulation of mercury in the tissues the use of sulphur waters throws it into the circulation, and they are thus of great service in cases of chronic mercurial poisoning.

The Rearing of Premature Children at the Charity Maternity Hospital.

The conditions to fulfil for the successful rearing of premature children—i.e., children born before term, between the sixth and ninth months, whose weight varies from 1500 grammes and less up to 2500 grammes—comprise three essential indications. First, to guard the infants against chill by means of incubation, massage, and hot baths. Secondly, to give them appropriate diet which should before all things consist of breast milk. Thirdly, to protect them from the results of infection to which their low powers of resistance expose them and at the same time to pay careful attention to their hygiene and to isolate them from every source of infection. Moreover, an important point is that when these children are born in a maternity charity they should be kept there during the whole time necessary for their complete development. It was by the application of these principles, and by following the rules so accurately laid down by Budin, that all the premature children born at the Charity Maternity Hospital between 1898 and 1907 were cared for. The results are as follows. Out of 735 children 616 left the hospital alive and well which gives a percentage of 83·80 survivals. The *consultations des nourrissons* at the hospital allowed 146 of these cases to be followed up over a range of time varying from one month to two years and advice and help to be given to the mothers in the task of bringing up the children. Of these 146 feeble children five died, a mortality of 3·42 per cent., so that the total survivals were 96·58 per cent. This proves that premature children can be brought up and can develop physically and intellectually in as great a proportion as full-term children. This result, which Budin's researches had already shown would occur, proves that, far from considering such children as a negligible quantity, we should strive to promote their development in every possible way. It is also desirable that in accordance with the opinion of M. Paul Strauss feeble children should be considered as "sick," and, like them, given the benefit of the law with regard to gratuitous relief, so that the indigent mother of a premature child can be helped and enabled to devote herself entirely to the difficult task of rearing the infant.

June 18th.

THE INTERNATIONAL COMMISSION ON SLEEPING SICKNESS.

AT the invitation of the Colonial Office an international conference was opened at the Foreign Office on June 17th, where representatives of the various African colonies and protectorates met to discuss the question of taking concerted action in dealing with sleeping sickness. The delegates taking part in the conference are:—

Great Britain.—Lord Fitzmaurice, Sir W. Foster, Mr. A. W. Clarke (Foreign Office), Mr. H. J. Read (Colonial Office), and Sir Patrick Manson.

Congo Free State.—Colonel Lantonnais (Vice-Governor-General), Commandant Tonneau, M. Rutten, and Dr. van Campenhout.

France.—Dr. Kermorgant, Dr. Paul Gouzion, Professor Blanchard, and Dr. Laveran.

Germany.—Herr von Jacobs (Imperial Colonial Office), Dr. Ehrlich, and Dr. Fulleborn.

Portugal.—Dr. Correa Pinto.

Sudan.—Colonel Hunter and Dr. Andrew Balfour (Gordon College, Khartum).

Lord FITZMAURICE is the president and delivered an address of welcome.

Obituary.

BENJAMIN LANE, L.R.C.P. LOND., L.R.C.S. IREL.,

BRIGADE SURGEON, ARMY (RETIRED).

Brigade-Surgeon Benjamin Lane, who for some years has lived in retirement at Cheltenham, died on June 12th at his residence in that town. He was the eldest son of Dr. W. Lane of Limavady, county Derry, and was born on June 4th, 1827. He entered the army in 1852 as assistant-surgeon and retired in 1882. He received for his services in the Burmese war of 1852–53 with the 80th Regiment the medal with clasp. He was present at the attack at Tomboo and gained distinction in the various operations in its vicinity. On one occasion, when the whole detachment at Tomboo was prostrate with fever, he devoted himself so whole-heartedly to the care of the sick that his assiduous attention to those under his care was singled out for particular commendation in General Orders by the commander-in-chief. In the storm and stress of the Indian Mutiny his sterling worth and inherent capacity to deal with the most untoward emergencies gained for him the well-earned reputation of an able and energetic officer. On March 5th, 1858, his zeal and experience were utilised at the action on the banks of the Jumna, for which he received the medal. For 14 years his duties kept him in close touch with the 4th King's Own Royal Regiment at home and abroad. He leaves three daughters and one son who is well known in the medical profession, Mr. W. Arbuthnot Lane.

Brigade-Surgeon Lane was buried in Cheltenham cemetery on June 15th and the ceremony was attended by the immediate relatives and by a great gathering of his old military and other friends, amongst these being General Winson, General Prendergast, Colonel Croker King, Commander Dillon, R.N., Lieutenant-Colonel Harvest, Colonel Farwell, Colonel Abbott, Colonel Burlton-Bennett, and Colonel Mortimer.

Medical News.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.—The ordinary Council of the above College on the 13th inst. conferred Diplomas of Fellow upon 26 candidates who passed in the subjects of Surgery, Surgical Anatomy, and Pathology at the recent examination, for which 63 candidates presented themselves. The following are the names and qualifications of the new Fellows of the College:—

Reginald George Turner, L.R.C.P., M.R.C.S., St. George's and London Hospitals; Stanley Edward Denyer, C.M.G., M.D., M.A., B.C. Cantab., L.R.C.P., M.R.C.S., D.P.H., Cambridge University and Guy's Hospital; Richard Horace Paramore, M.D. Lond., L.R.C.P., M.R.C.S., St. Bartholomew's Hospital; James Vere Arkle, L.R.C.P., M.R.C.S., New Zealand University and St. Thomas's Hospital; Frank Arthur Hepworth, M.A., M.B., B.C. Cantab., L.R.C.P., M.R.C.S., Cambridge University and St. Bartholomew's Hospital; William Lawrence Cripps, B.C. Cantab., L.R.C.P., M.R.C.S., Cambridge University and St. Bartholomew's Hospital; Francis Willoughby Goyder, M.B., B.C. Cantab., L.R.C.P., M.R.C.S., Cambridge University and St. Mary's Hospital; Frank Alexander Gallon Jeans, M.A., M.B., B.C. Cantab., L.R.C.P., M.R.C.S., Cambridge University and St. Bartholomew's Hospital; William Girling Ball, L.R.C.P., M.R.C.S., St. Bartholomew's Hospital; Herbert Wilberforce Perkins, L.R.C.P., M.R.C.S., L.D.S., Middlesex Hospital; Albert James Walton, B.Sc. Lond., L.R.C.P., M.R.C.S., London Hospital; Ivor Gordon Back, M.B., B.C. Cantab., L.R.C.P., M.R.C.S., Cambridge University and St. George's Hospital; John Clarke Mead, L.R.C.P., M.R.C.S., St. Bartholomew's Hospital; William Isaac Cumberlidge, B.A. Cantab., L.R.C.P., M.R.C.S., St. Bartholomew's Hospital; Ebenezer Ross Faulkner, B.A., M.D., C.M. Dalhousie, L.R.C.P., M.R.C.S., St. Thomas's Hospital; Paul Leon Giuseppi, M.B., B.S. Lond., L.R.C.P., M.R.C.S., St. Bartholomew's Hospital; Melville Birks, M.B., B.S. Adelaide, L.R.C.P., M.R.C.S., Adelaide University and London Hospital; Robert Dow Forbes, M.D., McGill University L.R.C.P., M.R.C.S., McGill University and St. Thomas's Hospital; Francis Edmund McKenty, M.D., C.M. McGill University, L.R.C.P., M.R.C.S., McGill University; David Thomas Barry, M.D. Royal University of Ireland, D.P.H., Liverpool University and London Hospital; Raymond Broadley Etherington-Smith, M.A., M.B., B.C. Cantab., Cambridge University and St. Bartholomew's Hospital; Arthur Charles Goodwin, M.B., M.Ch. Oxon., Oxford University and London Hospital; Richard Eugene Harcourt, M.D., M.Ch. Royal University of Ireland, Belfast and Liverpool University; John Swift Joly, M.B., B.Ch., B.A.O., M.D. Dublin, Dublin Unversity and London Hospital; Francis Scoble Mackenzie, M.B., Ch.B., Ch.M. Edinburgh, Edinburgh University, King's College, and London Hospitals; and Henry Herbert Rayner, M.B., Ch.B. Victoria, London Hospital and Manchester University.

Licences to practise Dental Surgery were also conferred by the Council on the undermentioned gentlemen who have completed the necessary examinations:—

Leonard Charles Attkins, Middlesex and National Dental Hospitals; Alfred Newman Balkwill, Charing Cross and Royal Dental Hospitals; Edgar Playle Barnett, Guy's Hospital; William Gordon Batt, Middlesex and National Dental Hospitals; Edwin Leonard Brown, Guy's Hospital; Reginald William Clayton Cooper, Arthur Basil Cross, and William Allison Cuttriss, Charing Cross and Royal Dental Hospitals; Harold John Dear, Guy's Hospital; Frederic Leonard Denty, Charing Cross and Royal Dental Hospitals; Rupert Woodward Elvy, D.D.S. Penn., St. Mary's Hospital; Alverstone Harold Gabell and Reginald Algernon Glindon, Guy's Hospital; William Henry Ireland and Cecil Augustus Joll, B.Sc. Lond., University College, Bristol; Jamshedji Jivanji Modi, L.M. & S. Bombay, Bombay University and Royal Dental Hospital; Lionel Alexander Burke Moore, Guy's Hospital; William Charles Augustus Ovey, Charing Cross and Royal Dental Hospitals; Ralph Redpath, Guy's Hospital; John Alfred Rose, Middlesex and National Dental Hospitals; Bertram Barnett Samuel, Guy's Hospital; Wilfrid Tom Sansom, Birmingham University; Thomas Lionel Smith, Guy's Hospital; Percy Sidney Charles Sutcliffe, Westminster and Royal Dental Hospitals; Hedley Clarence Visick, Guy's Hospital; and William Hubert Willsher, Middlesex and Royal Dental Hospitals.

UNIVERSITY OF CAMBRIDGE.—The late Professor Newton has bequeathed to the University his zoological collections, copyrights, and books, together with £1000 for the upkeep of the zoological library.—The general board proposes that two new lectureships, one in the physiology of the senses and the other in experimental psychology, shall be established in place of the lectureship in psychophysics now held by Dr. W. H. R. Rivers, of St. John's.—The honorary degree of Doctor of Science is to be conferred on a number of distinguished foreign geologists in connexion with the approaching centenary of the Geological Society.—The Raymond Horton-Smith prize for the best M.D. thesis of the year has been awarded to Dr. J. Mellanby, M.A., Emmanuel College. The subject was "The Properties of Diphtheria Antitoxin and its Relation to the Proteids of Normal Serum."—At Congregations on June 13th and 15th the following degrees were conferred:—

M.D.—T. G. M. Hine, King's; G. T. Western, Pembroke; J. Mellanby, Emmanuel; and E. B. Leech, Christ's.

M.B. and B.C.—F. Gayner, King's; H. P. Crampton and H. W. Wiltshire, Clare; and C. Cassidy, H. P. Gibb, and H. Dimock, Sidney Sussex.

M.B.—C. E. Droop, Trinity; H. C. Cameron, St. John's; J. W. Linnell, St. John's; A. R. Jordan, Clare; and E. Lloyd.

B C.—L. H. L. Mackenzie, Trinity.

D.Sc.—A. Scott.

FOREIGN UNIVERSITY INTELLIGENCE.—*Berlin:* Dr. Bockenheimer, Assistant in the Ziegelstrasse Surgical Clinic, Dr. Adolf Lazarus, *privat-docent* of Medicine, and Dr. Boas, *Sanitätsrat*, have been granted the title of Professor.—*Bonn:* Dr. Garré of Breslau, where he has only been for a single year, having succeeded the late Professor von Mikulicz-Radecki, has been appointed Professor of Surgery in succession to Dr. von Bergmann who goes to Berlin.—*Constantinople:* Dr. Wieting has been appointed Director of the Medical School in place of Dr. Deycke who has returned to Hamburg.—*Copenhagen:* Dr. Chr. Heyerdahl has been recognised as *privat-docent* of Neurology.—*Göttingen:* Dr. Knapp has been recognised as *privat-docent* of Psychiatry and Neurology.—*Greifswald:* Dr. Eduard Allard has been recognised as *privat-docent* of Medicine. Dr. August Martin, Professor of Gynæcology, is retiring at the close of the summer semester; Dr. M. Kochmann has been recognised as *privat-docent* of Pharmacology and Dr. Mangold of Jena as *privat-docent* of Physiology.—*Kazan:* Dr. Zimnitski of St. Petersburg has been appointed Extraordinary Professor of Medicine.—*Naples:* Dr. Alfonso Montefusco has been recognised as *privat-docent* of Infectious Diseases.—*Odessa:* Dr. Mikhael Diterikhs has been recognised as *privat-docent* of Orthopædic Surgery.—*Strasburg:* Dr. Georg Weill, *privat-docent* of Ophthalmology, has been granted the title of Professor.—*Vienna:* Dr. Schüller has been recognised as *privat-docent* of Mental and Nervous Diseases and Dr. Ludwig Wick as *privat-docent* of Balneology and Hæmatology.

THE COMPULSORY NOTIFICATION OF PULMONARY TUBERCULOSIS.—The question as to the desirability of the compulsory notification of pulmonary tuberculosis was answered in the affirmative at a conference of representatives from 28 of the 29 metropolitan borough councils held on June 6th in the Town Hall, Paddington, the Mayor of Paddington being in the chair. Mr. W. J. Nolan (Paddington), in moving that it is desirable that the notification of pulmonary tuberculosis should be compulsory, said that tuberculosis was infective and curable. He contended that compulsory notification was essential for providing the groundwork of future legislation and could be "gently worked" without interfering with the liberty of the subject. The conference before voting in favour of this motion rejected by 36 to 12 an amendment stating that it is desirable that voluntary notification of pulmonary tuberculosis should be general throughout Great Britain and Ireland. This amendment was moved by Dr. F. H. Alderson (Kensington) who declared that it was impossible to consider tuberculosis from the same standpoint as small-pox. The effect of compulsory legislation would be to make the unfortunate consumptive patient a "social leper" and sufficient sanatoriums could not be provided "without ruination to the ratepayers." Dr. A. J. Rice Oxley (Kensington) observed that the general public would not tolerate such a vexatious measure as compulsory notification which would be more difficult to enforce than vaccination. On the proposal of Dr. T. Orme Dudfield the conference agreed to the following :—

> That a sanatorium is needed for the open-air treatment of poor persons suffering from pulmonary consumption in the early stages of the disease, and should be provided by a central authority acting for the metropolis as a whole. That the managers of the Metropolitan Asylums Board, by reason of their practical experience in the management of hospitals for infectious disease, being eminently qualified for the position of such authority, the Local Government Board be requested to confer on, or if necessary to obtain for, the said managers power to act in that capacity. That the managers of the Metropolitan Asylums Board should also be empowered to use for *sanatorium* purposes the "Southern Hospital," recently erected by them at Carshalton, in the County of Surrey.

The following motions were also carried and a deputation was appointed to wait upon the President of the Local Government Board :—

> That application be made to the Local Government Board for an order to be made to include pulmonary tuberculosis among the diseases to be notified under Section 55 of the Public Health (London) Act, 1891, and to extend the provisions of Sections 60 to 65 of the above Act to pulmonary tuberculosis.
>
> That, in the opinion of this conference, it is desirable, in order to limit the spread of pulmonary tuberculosis, provision should be made for public inspection and control at its several sources, of the milk-supply of England, and that the Local Government Board be asked to make the Dairies, Cowsheds, and Milk Shops Order, 1885, and their amendments compulsory on local authorities.
>
> That application be made to the Local Government Board for an order to be made to extend the provisions of Section 69 of the Public Health (London) Act to pulmonary tuberculosis, in so far as it relates to the milking of cows and to the sale and distribution of milk.

DEATH OF A CENTENARIAN.—Mrs. Patience Harris died at King's Stanley, Gloucestershire, on June 3rd, aged 101 years.

UNIVERSITY OF OXFORD.—In a Convocation held on June 18th the honorary degree of D.Sc. was conferred upon Geheimrath Professor Dr. Paul Ehrlich, director of the Royal Institute for Experimental Therapeutics, Frankfurt on the Main. Dr. Ehrlich was presented by Professor A. E. H. Love, D.Sc., Sedleian Professor of Natural Philosophy.

MEDICAL MAGISTRATES.—Mr. Richard Harding, L.R.C.P. Edin., L.F.P.S. Glasg., of New Radnor, has been placed on the commission of the peace for the county of Radnor.—Mr. John Lloyd Davies, L.R.C.P. Lond., M.R.C.S. Eng., of Newport, and Mr. Evan Thomas, M.D. Lond., L.R.C.P. Lond., M.R.C.S Eng., of Newbridge have been placed on the commission of the peace for the county of Monmouth.

As we have already announced, a meeting to inaugurate an educational health and food campaign will be held at the Mansion House on June 26th, at 4 P.M., under the chairmanship of the Lord Mayor, and under the auspices of the Bread and Food Reform League and other societies. It is desired to institute a vigorous propaganda against the national ignorance about the value of articles of diet, the careless consumption of adulterated food, and the neglect of elementary laws of hygiene.

A SCIENTIFIC EXHIBITION.—An exhibition of engineering models, optical, electrical, and scientific instruments, technical education appliances, and tools is to be held at the Royal Horticultural Hall, Vincent-square, Westminster, London, S.W., from Oct.. 22nd to 26th inclusive. In addition to exhibits by the leading makers of the above-named goods there will be an important loan collection of interesting experimental and exhibition models and apparatus and also lectures and demonstrations in various branches of applied science. The exhibition is being organised by Messrs. Percival Marshall and Co., 26–29, Poppin's-court, Fleet-street, London, E.C., who will be pleased to give further particulars on application.

DONATIONS AND BEQUESTS.—By the will of Mrs. Helen Grundy the Bury Dispensary Hospital will benefit by the sum of £3000 and the Robinson Kay Hospital for Incurables by £1500.—Miss Mary Ann Mellor Davidson has by will left £1000 to St. Mary's Hospital, Quay-street, Manchester; £1000 to the Manchester Royal Infirmary and Dispensary; £1000 to the Stockport Infirmary; £500 to the Manchester Royal Eye Infirmary; £500 to the Manchester and Salford Blind Aid Society; £500 to the Manchester and Salford Hospital for Skin Diseases; £500 to the Manchester and Northern Hospital for Women and Children; £500 to the Manchester Hospital for Consumption and Diseases of the Throat and Chest; £500 to St. Mary's Home, Manchester; and £500 to the General Hospital and Dispensary for Sick Children, Pendlebury.—By the will of Mrs. Byrne the sum of £600 is bequeathed to the Royal Sick Children's Hospital, Aberdeen, to found a cot to be called the "Elsie Mary Byrne cot," while to Morningfield Hospital, Aberdeen, the same lady has left the sum of £200.

PROLONGATION OF LIFE IN ICELAND.—Mr. J. Vidalin, British consul at Reykjavik, in his annual report to the Foreign Office, mentions that the population of Iceland in 1905 was 80,500, and adds: "A very interesting fact is the prolongation of human life. The medium age in the country in the period 1830–49 was 33 years; in 1851–60 it was 35·4 years; in 1891–1900 it was 55·9; and in 1901 it was 61·8. The chief reasons for this prolongation of life are the increase in the number of physicians and the strong measures against the introduction of infectious diseases into the country."

INSTITUTE OF HYGIENE.—A meeting of this institution was held at 34, Devonshire-street, Harley-street, W., on June 18th, when Sir Dyce Duckworth delivered a lecture on Nursing and the Needs of the Invalid. In the course of his remarks he said that we had only to cross the Channel to find how sadly inferior and belated are the nursing arrangements in most of the continental countries where, with occasional exceptions, the needs of the patient are very imperfectly met and both the *matériel* and *personnel* are clumsy, often insanitary and inadequate, though the administration may be in devoted, if untrained, hands. He said that we required more nurses fully trained in large hospitals. The primary duty of the nurse was the general welfare of the patient in every detail but she should be properly housed, comfortably fed and provided for, and not be treated as a menial. He then proceeded to give at length the various duties of a nurse.

THE LONG GROVE ASYLUM.—The new Long Grove Asylum at Epsom, erected by the London County Council, has been recently completed and the first batch of patients were received this week. The asylum is the tenth for the County of London and was designed by Mr. George T. Hine. The buildings will accommodate 2020 patients, of whom 650 will be lodged in villas. The wards are divided into the following classes: sick and infirm, acute, refractory epileptics, and chronic quiet and working patients. Two villas, taking 50 patients each, are hospitals designed for the reception of new cases and their treatment if curable, whilst two, each taking 25 patients, form probationary convalescent homes for cases so treated. The main block wards are in continuous buildings on the pavilion principle and are all intercommunicating as well as being connected with main corridors. The administrative buildings and offices are suitable, whilst full provision has been made for the accommodation and recreation of the staff. The recreation hall for patients is 120 feet by 60 feet. The asylum includes a farm with buildings, a detached chapel, a residence for the medical superintendent, an isolation hospital, and complete workshops and laundry buildings. The electricity for lighting and power purposes is generated at the central station of the Horton estate. The water tower is 130 feet high and contains tanks holding 80 000 gallons. The entire cost, excepting land and equipment, is estimated at £490,000 —i.e., £243 per bed.

Parliamentary Intelligence.

NOTES ON CURRENT TOPICS.

The Wounded and Sick in War.

THE terms of the International Convention for the Amelioration of the Condition of the Wounded and Sick in Armies in the Field, which was signed at Geneva on July 6th, 1906, are set forth in an official paper presented to both Houses of Parliament. The British ratification of the Convention was deposited at Berne on April 16th, 1907. The Convention has already been ratified by Siam, the United States o America, Russia, Italy, Switzerland, the Congo Free State, and Germany. The formal adhesion to the Convention has still to be given by many other States which took part in the conference at Geneva last year.

Breathing Appliances in Mining Disasters.

The first report of the Royal Commission which was appointed to inquire into certain questions relating to the health and safety of miners is entirely devoted to the subject of breathing appliances for use in mines at times of explosions and emergency. This matter was brought strikingly before public attention at the time of the Courrières disaster, when a rescue corps from Westphalia proceeded to the French mine with appliances for succour and relief. The Commission has utilised the experience gained in the use of various types of breathing apparatus in mines on the continent. In connexion with the investigations of the Commission the director of the Lister Institute kindly allowed experiments to be conducted at the institute. Dr. A. E. BOYCOTT, who, as the report states, was specially qualified for making an examination of the various breathing appliances by a practical knowledge of the physiology of respiration and considerable experience of underground conditions, conducted a series of experiments in great detail and his elaborate description of his work is printed as an appendix to the Blue-book. The Commissioners, after considering the evidence put before them, come to the conclusion that the question of the provision of breathing appliances demands the serious attention of the mining industry. However, they are of opinion that sufficient advance has not been made to justify making the provision of the appliances compulsory. A good deal of experience is required as to their working and as to the best system of training men before the value of their use can be properly appreciated. At the same time they express confidence that the necessary steps towards a systematic use of the appliances will be taken by the mine-owners of the United Kingdom without delay.

The College of Science.

Dr. DONALD MACALISTER, President of the General Medical Council, who recently became Principal of the University of Glasgow, has been appointed by the Crown to the governing body of the new College of Science at South Kensington. His name was included in the list announced by the Prime Minister in the House of Commons on Monday.

Purity of Milk supplies (Scotland) Bill.

The text of the Purity of Milk-supplies (Scotland) Bill, introduced into the House of Commons recently by Mr. WATT, has been printed. The measure is supported by Sir ANDREW TORRANCE, Mr. PRICE, Mr. MCCALLUM, and Mr. HALLEY STEWART. The object of the Bill is to insure the purity of milk-supplies in rural and urban districts of Scotland. One of the clauses lays down that no person shall sell for human food the milk of any cow suffering from chronic wasting disease or any disease of the udder or ulceration of the teats. There are further provisions in the Bill for the notification of disease in cows and for the prevention of infection or contamination of the milk.

The Investigation of Cancer.

Last week Captain FABER put a question on the notice paper of the House of Commons in which he asked the Prime Minister whether he could see "his way to appoint a Royal Commission to inquire into the prevailing scourge of cancer." The Prime Minister, through his private secretary, intimated to Captain FABER that he would take some days to consider his answer, and up to Wednesday night the honourable Member had received no further communication on the subject. The delay of the Prime Minister in sending a reply to the question has raised hopes amongst many members that the Government will assent to some such investigation as Captain FABER suggests, but no formal and official announcement has been made.

HOUSE OF COMMONS.

THURSDAY, JUNE 13TH.

Women Medical Referees.

Mr. HENRY J. WILSON asked the Secretary of State for the Home Department whether he had taken, or would take, into consideration the propriety of appointing some women medical referees under the Workmen's Compensation Act which will come into force on July 1st, especially in cases or districts where women were largely employed.—Mr. GLADSTONE answered: I am not aware that any necessity for such appointments has been found to exist under the Act of 1897, which applied to a large number of women employed in factories, but I shall be glad to take the matter into consideration.

Hygiene in Schools.

Mr. HARMOOD-BANNER asked the President of the Board of Education whether his attention had been called to the demand for the compulsory introduction of the teaching of hygiene and temperance into the curriculum of the elementary schools; and whether he intended by legislation or administrative action to carry through a scheme in reference thereto with as little delay as possible.—Mr MCKENNA replied: I have received numerous representations urging the necessity of extending the teaching of hygiene in elementary schools. The code at present lays down that physical training should be included in the curriculum for scholars other than infants and should be accompanied by instruction in the elementary rules of personal health in respect of food, drink, cleanliness, and fresh air, and the volume of "Suggestions for the Consideration of Teachers," which was issued by the Board a few years ago, included an outline scheme for the teaching of hygiene and temperance I am considering how numerous difficulties connected with the teaching of this subject can be surmounted and I hope to derive considerable assistance in this from the International Congress upon School Hygiene which will meet in London in August.

FRIDAY, JUNE 14TH.

The Medical Inspection of School Children.

During the afternoon the House considered the Education Acts Amendment Bill as amended in Standing Committee. This is the measure which was introduced by Mr. W. Rea to make provision for the medical inspection and treatment of school children.

Sir F. BANBURY moved as an amendment to omit Clause 1, which contained a provision for the medical inspection of children "before or at the time of their admission" to a public elementary school. He thought the clause went too far, as under it the local education authority appeared to be empowered to give a medical man a roving commission to examine children who, he might think, required medical examination or attendance.

Captain CRAIG seconded the amendment. He contended that the clause merely amounted to securing medical attendance for children from the day they were born.

Mr. W. REA pointed out that the Bill was composed of two uncontentious clauses from the Education Bill of last year. He could assure honourable Members that the fears expressed with regard to the extent of the operation of the clause under discussion were groundless. The words providing for the medical inspection of children, "before or at the time of their admission to a public elementary school," must be read in conjunction. He was informed that the introduction of the word "before" in this connexion could not be construed into meaning that State medical inspection of children was permitted from the time they were born.

After some discussion the amendment was by leave withdrawn.

Sir P. MAGNUS moved an amendment to alter the phraseology of the clause so that it should be provided that the medical inspection should take place "at any time within 12 months after" the child's admission to school.

Captain CRAIG seconded the amendment.

Sir WILLIAM COLLINS considered that the best time for the medical inspection to take place was shortly after the admission because teachers, when they had become familiar with the children, were able to indicate to the medical officer defects from which they thought the children were suffering.

Mr. LOUGH (Parliamentary Secretary to the Board of Education) suggested that some such words as "immediately before, about the time of, or as soon as possible after" the admission of the child would meet the case

The amendment was withdrawn and the words suggested by Mr. Lough were inserted in the Bill.

Mr. ASHLEY moved as another amendment that a provision should be inserted in the Bill laying down that expenses incurred under the Act for attending to the health and physical condition of a child should be recoverable from the parent in a court of summary jurisdiction

Sir F BANBURY seconded the amendment. However, after some discussion it was defeated by 229 votes to 39. This completed the report stage of the Bill.

MONDAY, JUNE 17TH.

The Food Regulation Bill.

Mr. ALDEN asked the President of the Local Government Board, in view of the non-introduction of the Food Regulation Bill, whether he could state the degree in which his Bill had the support of the leading sanitary authorities and medical officers of the country and the extent to which it was opposed by such authorities.—Mr BURNS replied: My honourable friend is under a misapprehension. The Bill to which he refers was introduced this session. It was brought in some time since and is awaiting second reading. I have received several communications from the sanitary authorities in favour of the Bill and none against it.

The Teaching of Hygiene in Scottish Schools.

Mr. WEIR asked the Secretary for Scotland whether the Scottish Education Department would be represented at the International Congress upon School Hygiene which will meet in London in August; and whether he would consider the expediency of arranging for the compulsory teaching of hygiene and temperance in the elementary public schools in Scotland.—Mr. SINCLAIR answered: The department proposes to be represented at the Congress. It is not prepared at present to make the teaching of the subjects mentioned compulsory, but will carefully consider the reports of any discussions on the subject at the Congress.

Factory Inspection in Belfast.

Mr. CHARLES DUNCAN asked the Chief Secretary to the Lord Lieutenant of Ireland whether, seeing that the medical officer of health of the city of Belfast recently refused to take action in a case of factory inspection, and that a special sanitary inspector was sent to Belfast by the Government, any report had yet been issued by his department on this case; and, if not, whether any promise could be given as to the date of its publication.—Mr. BIRRELL sent the following written reply to the honourable Member: The inspection of factories is a matter which concerns the Home Secretary to whom any inquiry on the subject should be addressed As regards the latter part of the question it is assumed that the honourable Member intends to refer to the Commission of Inquiry which is at present investigating the general sanitary administration of Belfast. The Commission has not yet finished taking evidence and it cannot be said when its report will be ready.

TUESDAY, JUNE 18TH.

The Lunacy Commission.

Sir JOHN TUKE asked the Secretary of State for the Home Department whether, pending the production of the report of the Royal Commission on the Care and Control of the Feeble-minded, and pending legislation founded on the said report, he would take any steps to supplement the Lunacy Commission so as to relieve the existing congestion in the department and to procure adequate inspection of asylums.—Mr. GLADSTONE said in reply: The number of the Commissioners in Lunacy is fixed by statute and while I am fully alive to the fact that the great increase in the duties which they have to carry out has caused a considerable congestion of business, to meet which an addition to their staff may be required, I could not initiate legislation pending the presentation of the report of the Royal Commission.

MEDICAL AND DENTAL COMPANIES.

The Select Committee of the House of Lords, which was appointed to take evidence in connexion with the Prohibition of Medical Practice by Companies Bill and the Dental Companies (Restriction of Practice) Bill, held its concluding public sitting on Thursday, June 13th. Lord HYLTON was again in the chair and all the other members of the committee were present.

Mr. MUIR MACKENZIE, who was lately legal assessor to the General edical Council, was the first witness examined. He stated that he ad been concerned in the drafting of both Bills. He pointed out that evidence against the Prohibition of Medical Practice by Companies ill had been offered to the committee. So far as his experience went ere would be many companies affected by the Bill.

Lord Knutsford: With regard to the Dental Bill, has your atten-on been drawn to the fact that a certain number of dental companies, lthough composed of unqualified persons, appear to be *bonâ fide* nd appear also to do a great deal of good in districts where there are o registered practitioners at present? The evidence is very strong at there are such companies legitimately formed and carried on, no oubt, by unqualified persons who nevertheless have had some training.

Mr. Muir Mackenzie: I have never come across a company of this rt carried on to the advantage of the public, and the mischief of nqualified men, however much their experience is assumed to be, is, am convinced, a very grave one. I have seen this, not only as a lawyer the course of a very large practice at the Bar, but also when I was nnected with the General Medical Council.

Lord Knutsford: From your experience would you consider that here should not have been in the Acts of 1878 and 1858 exemptions for ersons who were in *bonâ-fide* practice? In 1858 persons who had not een on the Register were allowed to go on it, and in 1878 the same hing happened.

Mr. Muir Mackenzie: That was the case, but it was not to the dvantage of the public, if your lordship will permit me to say so. He ent on to say that ignorant and incompetent men had in this way een placed on the Register.

Lord Knutsford: You think on general principles that it is not esirable that there should be companies of this sort?

Mr. Muir Mackenzie: I think that is a great disadvantage to the ublic.

Lord Knutsford: You would not therefore agree with the Dental Bill?

Mr. Muir Mackenzie: As a member of the public I would prefer he Bill to no Bill at all, but I would prefer the extension of the principle of the Medical Bill.

Lord Knutsford: You would not make any exemptions in the case of the dental companies.

Mr. Muir Mackenzie: I do not think it is possible to draft pro-isions for those exemptions. He could not agree that any company f unqualified surgeons, physicians, or dentists was carrying on a *bonâ-fide* practice. If the committee asked him his opinion he would say that the introduction of exemptions into the Bill would lead to the possibility of abuse.

The Chairman: I rather gather that you hold that the establish-ment and the working of these dental companies are contrary to the intentions of the Act of 1878. That is your principal contention.

Mr. Muir Mackenzie: Certainly.

The Chairman: Under the Act of 1878 the legislature intended to direct that only qualified dental practitioners should be allowed to practise, and what has been going on since has been contrary to the intentions of the legislature?

Mr. Muir Mackenzie: No doubt that was the intention. However, in the Act of 1858 and in the Act of 1878 the legislature stopped short of making it a misdemeanour for unqualified men to practise. However, they imposed disabilities.

Lord Knutsford: The unqualified man cannot recover fees, for instance.

Mr. Muir Mackenzie: No.

The Chairman: Some evidence has been given to us tending to suggest that if we passed the Prohibition of Medical Practice by Companies Bill in its present form our object might be defeated by any of the present joint-stock companies being dissolved and private companies being formed which would in future do exactly what joint-stock companies do at present.

Mr. Muir Mackenzie: The answer is there is no such thing as a private company. The joint-stock company is an incorporated body. A company apart from that kind of company is merely the persons who compose it.

The Chairman: You see no danger in the phrase "to prohibit joint-stock companies"?

Mr. Muir Mackenzie: No, none at all.

Mr. Lushington, legal assessor to the General Medical Council, gave evidence on several of the legal points involved in the Bills.

The Chairman: If you have not got a joint-stock company to deal with I suppose it is a partnership?

Mr. Lushington: Then it is a question of individuals and the Dentists Act applies. He thought if the Dental Bill passed without exemptions that a man who had been practising through a company could go on in his own name as an unregistered practitioner. Their lordships had been told that companies had been formed for the purpose of obtaining additional capital, but that course was also taken for the purpose of screening the assets from attack. He did not see what more capital was required for in these cases except for advertising. He would be surprised to hear that there was any part of England where there were not enough registered dentists for the work. There were very few districts where there were no registered dentists.

Lord Knutsford: We have very strong evidence to the contrary.

Mr. Lushington: The Registrar to the General Medical Council could give you evidence on that point, if you desire it, because he knows the addresses of registered men.

Mr. W. H. Winterbotham, solicitor to the General Medical Council, went into the witness-chair and submitted that in two specific cases which had been brought before the committee, the companies could be carried on as private concerns.

Mr. F. Butterfield, secretary to the Incorporated Society of Extractors and Adapters of Teeth, explained the conditions under which membership of that organisation was obtained. He stated that there were about 1750 towns and villages in Great Britain with populations ranging from 300 to 20,000 or 30,000 where there were no registered dentists established. He contended that good work was done by unregistered men in filling up the deficiency and gave instances of various towns in support of his contention.

Mr. Winterbotham was recalled.

The Chairman: Mr. Winterbotham, the committee has had before them the question of whether herbalists are affected or not by the Medical Bill. We held that they are not but we should like to have your opinion on the point.

Mr. Winterbotham: I listened to the evidence given by Mr. Blunt, and I gather that the company for which he spoke was not a practising company but an association of herbalists formed for their own mutual benefit. He said that they individually practised. The company does not practise and therefore it would not be affected.

The Chairman: We do not touch their practice as individuals. That is left untouched.

Mr. Winterbotham: Yes.

Dr. D. MacAlister, President of the General Medical Council, was recalled. In answer to the Chairman, he stated that the General Medical Council had no power to deal with any unqualified or unregistered person whatever.

Lord Knutsford: The only association of herbalists that has been brought under the notice of the committee is one which would not come under the Medical Bill?

Dr. MacAlister: They may come under the Apothecaries Act if they prescribe and dispense medicine. We have nothing to do with the administration of that Act. He further stated that the Bill gave no power to the General Medical Council which it did not at present possess.

This concluded the hearing of the evidence before the committee and the members then sat in private for the purpose of considering the Bills and their recommendations on them.

VACCINATION BILL.

One of the Standing Committees of the House of Commons on Wednesday, June 12th, took up the consideration of the Vaccination Bill, the object of which is to substitute a statutory declaration for the certificate of exemption on the grounds of conscientious objection required under the Act of 1898. Mr. Laurence Hardy was in the chair.

Several amendments, including one to extend the application of the Bill to Scotland, were ruled out of order by the Chairman as being beyond the scope of the measure.

Sir William Collins moved an amendment to Clause 1 of the Bill (which is the operative clause) with a view to making it legal for the parent to make the statutory declaration of conscientious objection before the registrar of births and deaths at the time of the registration of the birth. He stated that he intended that the commissioners for oaths and magistrates should still be competent to receive the declaration, but on the ground of additional facilities he wished to add the registrars to them. The father of a child was brought into relationship with the registrar when he registered the birth within six weeks of its occurrence, and that provided, as it were, the time and place at which the declaration of conscientious objection might be made.

Dr. Macnamara resisted the amendment as undesirable. He remarked that the Bill was not brought forward to take up the cause of the vaccinationist or of the antivaccinationist. It was to put an end to the cross-examination of applicants for certificates which had taken place in courts.

Sir John Tuke said that if the amendment were carried they might just as well repeal the whole of the Vaccination Acts which was, he believed, the object of several members of the committee.

Mr. Burns (President of the Local Government Board) declared that the object of the Bill as conceived by the Government would to a great extent be damaged and the existence of the Bill threatened if the amendment was carried. In his judgment the stipendiary magistrates, the commissioners for oaths, and the justices of the peace were far better qualified to receive the declaration of conscientious objection than was the registrar who might be a vaccination officer. A child's birth had to be registered in six weeks but vaccination need not take place for four months. However, the amendment would place a strong temptation upon the parent to register the birth and make the declaration at one visit. In that way they would practically diminish the discrimination of the parent. If the Bill was to become law this session he would appeal to honourable Members not to press the amendment.

On a division the amendment was rejected by 16 votes to 15.

After several minor amendments had been discussed

Mr. Pickersgill moved an amendment to permit either of the parents or "other person" to make a statutory declaration. He argued that it was often inconvenient for the father of the child to travel to a magistrate if there was none in his vicinity and thereby expense was incurred.

Dr. Macnamara, speaking as the representative of the Local Government Board, said that the amendment would strike a revolutionary blow at the whole English legal practice. Now an exemption was granted to a person who was liable. Here it was proposed to grant an exemption to a person who was liable through a person who was not liable.

On a division the amendment was carried by 16 votes to 14, the Government being thus placed in a minority of two.

The committee shortly afterwards adjourned.

The consideration of the Vaccination Bill was resumed by a Standing Committee of the House of Commons on June 18th, Mr. Laurence Hardy being in the chair.

Sir Henry Craik moved an amendment to the effect that the statutory declaration required by the Bill should be made before a justice of the peace only. He remarked that if a person had any conscientious objection to vaccination surely it would not be too much to ask that he should have the courage of his conviction and publicly declare his objection in open court.

Mr. Burns said that the amendment would seriously interfere with the scope of the Bill and therefore he could not accept it.

The amendment was by leave withdrawn.

Mr. Ashton moved a further amendment to the effect that the statutory declaration of conscientious objection could be legally made to the chairman of a parish council. However, this proposal was withdrawn after some discussion.

Sir William Collins then moved an amendment to the effect that exemption should be granted on the ground that the parent "conscientiously objected to the vaccination of the child." The provision in the Bill is that exemption should be granted on the ground that the parent "conscientiously believes that vaccination would be prejudicial to the health of the child." The honourable Member said that his amendment would limit the declaration to one of a simple objection to vaccination. As a member of the Royal Commission on Vaccination he said that this would be quite in harmony with its recommendations. The evidence before that Commission disclosed that the objection to vaccination was not entirely based upon the fear of physical injury. Dr. Creighton, who had written the article on vaccination in the *ninth edition of the Encyclopædia Britannica*, had rather based his objections on the ground that cow-pox was not a specific against small-pox. There were also objections on the ground of the impermanence of the protection of vaccination and some parents objected on the ground of the tender age of the child at which the present law of vaccination was enforced. He pointed out that in the case of the Education Acts there was no formula required of the special ground of conscientious objection. He might also add that in Germany the child need not be vaccinated till after the first year of life.

Sir JOHN TUKE said that there had been many attempts to broaden the basis of the Bill but none would broaden it more than this amendment would. He would not follow Sir William Collins into medical arguments but he would strongly press the Government not to accept the amendment. He referred to the condition of Scotland, where about 95 per cent. of that educated nation were vaccinated.

Mr. LUPTON remarked that besides the objections mentioned by Sir William Collins there ought to be taken into account the objections which many people had to vaccination on religious grounds. They did not believe in introducing diseases of any kind into the bodies of their children.

Mr. NAPIER pointed out that the amendment would open up the whole question of vaccination. The Members of the House of Commons would not be inclined at this stage of the session to enter into the consideration of such a large subject. However, he was anxious that the scandal which had arisen in the courts with regard to the granting of certificates of exemption should be put a stop to and therefore he did not want to risk the loss of the Bill by the introduction of the amendment.

Mr. BURNS said that if once they opened the flood-gates of medical difference for and against vaccination they would have to sit longer than the Royal Commission itself did. Personally he was, and had ever been, an antivaccinationist. It was because he shared the bulk of the views expressed by those who held these opinions that he would urge the committee not to jeopardise this Bill which had been brought in with cool and calculated deliberation to remove an admitted grievance. This would not be done if this medical controversy was entered upon. It would be absurd for any of them to say that this was the last word in the vaccination controversy. If he were to accept the amendment of Sir William Collins he was afraid it would be the last word on this particular Bill this session. He appealed to his honourable friend not to press the amendment which if set loose in the House of Commons would prevent the Bill getting through.

Mr. J. RAMSAY MACDONALD said that he had himself experienced a difficulty in making a declaration which limited the objection to the belief that vaccination would be prejudicial to the child. How, he might ask, could a layman know whether vaccination would prejudice the health of his child? He might also point out that there was no conscientious objection allowed in Scotland. Sir John Tuke must take that into account when he talked of 95 per cent. of the people there being vaccinated.

Sir WILLIAM COLLINS, in view of the statement made by the President of the Local Government Board, asked leave to withdraw his amendment.

The amendment was by leave withdrawn.

Mr LUPTON moved an amendment which was designed to give power to parents to make a declaration under the Bill with regard to their children who were born before it came into operation in January, 1908

Mr. BURNS opposed the amendment, which was rejected by 21 votes to 11.

After some further discussion the proceedings on the Bill in committee were completed and it was ordered to be reported to the House as amended.

Appointments.

Successful applicants for Vacancies, Secretaries of Public Institutions, and others possessing information suitable for this column, are invited to forward to THE LANCET *Office, directed to the Sub-Editor, not later than 9 o'clock on the Thursday morning of each week such information for gratuitous publication.*

COURT, E. P., M.R.C.S., L.R.C.P. Lond., has been appointed Certifying Surgeon under the Factory and Workshop Act for the Horsmonden District of the county of Kent.

DRURY, G. H., M.B., M.S. Edin., has been appointed Medical Officer and Public Vaccinator for the Fifth District of the Wells (Somerset) Union.

FANNING, J. J., L.R.C.P. & S. Edin., L.F.P.S. Glasg., has been appointed Certifying Surgeon under the Factory and Workshop Act for the Birr District of King's County.

FLETCHER, G. W. MORGAN, L.D.S. R.C.S. Eng., has been appointed Honorary Dental Surgeon to the Bristol Royal Hospital for Sick Women and Children.

GEDDIE, DAVID WATSON, M.A., M.B., C.M. Aberd., has been appointed Anæsthetist to the Royal Sick Children's Hospital, Aberdeen.

GOODWYN, HENRY, L.R.C.P., L.R.C.S., L.M. Edin., has been appointed Medical Officer for Bovey Tracey and Ilsington by the Newton Abbot (Devon) Board of Guardians.

LLEWELLYN, THOMAS LISTER, M.D., B.S. Lond., L.R.C.P., M.R.C.S., has been appointed Medical Officer for the Powell Duffryn and Rhymney Iron Companies (Monmouthshire).

LOCKETT, REGINALD FREDERICK, L.D.S. R.C.S. Eng., has been appointed Honorary Dental Surgeon to the Clevedon, Tickenham, Walton, and Kenn Dispensary.

LYON, T. M. M., M.D. Edin., has been appointed Certifying Surgeon under the Factory and Workshop Act for the Mid-Calder District of the county of Edinburgh.

PEDDIE, C., L.R.C.P. & S. Edin., L.F.P.S. Glasg., has been appointed Certifying Surgeon under the Factory and Workhop Act for the Withnell District of the county of Lancaster.

PORTEOUS, HERBERT LLEWELLYN, L.R.C.P. Lond., M.R.C.S., has bee appointed a District Medical Officer by the Stroud (Glouceste shire) Board of Guardians.

RICHARDS, JOHN, M.B., F.R.C.S. Edin., has been appointed Medic Superintendent of the Joint Counties Asylum, Carmarthen.

RICHARDS, MORGAN, M.B., B.S. Durh., has been appointed Clinic Assistant to the Chelsea Hospital for Women.

SPAIGHT, HENRY WILLIAM, L.R.C.P., L.R.C.S., L.M. Irel., has bee appointed District Medical Officer for the Helston (Cornwal Board of Guardians.

VISGER, CHARLES, L.R.C.P. Lond., M.R.C.S., has been appointe Medical Officer to the Clevedon, Tickenham, Walton, and Ken Dispensary.

WILLCOX, W. H., M.D. Lond., M.R.C.P. Lond., has been appointe Physician to Out-patients at St. Mary's Hospital.

Vacancies.

For further information regarding each vacancy reference should b made to the advertisement (see Index).

AYR DISTRICT ASYLUM.—Junior Assistant Physician, unmarried. Salary £120, with board, apartments, and laundry.

BERMONDSEY MEDICAL MISSION.—Lady Assistant for six months, with board and lodging.

BOLTON INFIRMARY AND DISPENSARY.—Junior House Surgeon. Salary £100 per annum, with apartments, board, and attendance.

BRADFORD POOR-LAW HOSPITAL AND WORKHOUSE.—Resident Assistant Medical Officer, unmarried. Salary £100, with rations, apartments, and washing.

BRADFORD ROYAL INFIRMARY.—Resident Surgical Officer. Salary £150 per annum.

BRIGHTON, SUSSEX COUNTY HOSPITAL.—Second House Surgeon, unmarried. Salary £60 per annum, with board, residence, and washing.

BURNLEY, VICTORIA HOSPITAL.—Resident Medical Officer. Salary £100 per annum, with residence, board, and washing.

CAMBRIDGE, ADDENBROOKE'S HOSPITAL.—Assistant House Surgeon for six months. Salary £50 per annum, with board, residence, and laundry.

CANCER HOSPITAL, Fulham-road, S.W.—Medical Officer in Charge of the Electrical Department. Salary £26 5s. per annum

CARMARTHENSHIRE INFIRMARY.—Resident Medical Officer, unmarried. Salary £100 per annum, with apartments, board, attendance, fire, gas, and washing.

COVENTRY AND WARWICKSHIRE HOSPITAL.—Junior House Surgeon for six months, renewable. Salary £60 per annum, with rooms, board, washing, and attendance.

EAST LONDON HOSPITAL FOR CHILDREN AND DISPENSARY FOR WOMEN, Shadwell, E.—Assistant Surgeon. Also Second Medical Officer to the Casualty Department. Salary at rate of £40 per annum.

EDMONTON WORKHOUSE, Upper Edmonton.—Assistant Medical Officer. Salary £180 per annum.

EGYPT. Sub-Inspector of Ophthalmic Hospitals, unmarried. Salary £500 a year.

ENNISKILLEN, FERMANAGH COUNTY HOSPITAL.—House Surgeon. Salary £52 per annum.

EVELINA HOSPITAL FOR SICK CHILDREN, Southwark, S.E.—Clinical Assistants.

GLOUCESTER, GENERAL INFIRMARY AND GLOUCESTERSHIRE EYE INSTITUTION.—Senior House Surgeon. Salary £100 per annum, with board, residence, and washing.

GREAT NORTHERN CENTRAL HOSPITAL, N.—Honorary Medical Officer in Charge of Electrical Department.

GUILDFORD, ROYAL SURREY COUNTY HOSPITAL.—House Surgeon. Salary £100, with board, residence, and laundry. Also Assistant House Surgeon. Salary £50, with board, residence, and laundry.

HOSPITAL FOR SICK CHILDREN, Great Ormond-street, London, W.C.—House Surgeon, unmarried, for six months. Salary £20, with board and residence.

HULL, ROYAL INFIRMARY.—Casualty House Surgeon. Salary £50, with board and lodging.

INDIAN MEDICAL SERVICE.—An Examination for not less than 11 Commissions.

KIRKBURTON, NEAR HUDDERSFIELD, STORTHES HALL ASYLUM.—Locum Tenens for two months. Salary £3 3s. per week, with board, lodging, and attendance.

LEEDS UNION INFIRMARY, Beckett-street.—Assistant Medical Officer, unmarried. Salary £100 per annum, with board, washing, apartments, and attendance.

LEICESTERSHIRE AND RUTLAND ASYLUM, Leicester.—Senior Assistant Medical Officer, unmarried. Salary £150, rising to £200, with board, apartments, and washing.

LINCOLN COUNTY HOSPITAL.—Junior House Surgeon, unmarried, for six months. Salary £25, with board, residence, and washing.

LIVERPOOL EYE AND EAR INFIRMARY.—House Surgeon. Salary £80 per annum, with board and lodging.

LIVERPOOL WORKHOUSE, Brownlow Hill.—Assistant Medical Officer. Salary £80 per annum, with rations.

LONDON FEVER HOSPITAL, Liverpool-road, N.—Assistant Resident Medical Officer. Salary £120 per annum, with board and lodging.

LOUGHBOROUGH AND DISTRICT GENERAL HOSPITAL AND DISPENSARY.—Resident House Surgeon. Salary £100 a year, with rooms, attendance, board, and washing.

MAIDSTONE, WEST KENT GENERAL HOSPITAL.—Assistant House Surgeon, unmarried. Salary £80, with board and lodging.

NATIONAL HOSPITAL FOR THE PARALYSED AND EPILEPTIC, Queen-square, Bloomsbury.—Senior and Junior House Physicians. Salary £50 per annum, with board and residence in each case.

NEWCASTLE-ON-TYNE DISPENSARY.—Visiting Medical Assistant. Salary £160.

Newport and Monmouthshire Hospital.—Junior Resident Medical Officer. Salary £80 per annum, with board, residence, and laundry.

Norfolk and Norwich Hospital.—Assistant House Surgeon for six months. Salary £20, with apartments, board, and laundry.

Oldham Workhouse.—Resident Medical Officer, unmarried. Salary £150 per annum, with residence, coal, gas, rations, washing, and attendance.

Queen Charlotte's Lying-in Hospital, Marylebone-road, N.W.—Resident Medical Officer for four months. Salary at rate of £60 per annum, with board, residence, and washing.

Royal Institute of Public Health.—Demonstrator of Comparative Pathology and Bacteriology.

St. Mary's Hospital, Paddington, W.—Curator of the Museum and Assistant Pathologist. Salary £100 per annum.

St. Pancras and Northern Dispensary, 126, Euston-road.—Honorary Surgeon for Throat, Nose, and Ear Cases.

Scarborough Hospital and Dispensary.—Junior House Surgeon. Salary £80 per annum, with board and residence.

Sheffield Fever Hospitals.—Junior Assistant Medical Officer. Salary £130 per annum, with board, lodging, and washing.

Sheffield, University of.—Demonstrator in Physiology. Salary £150 per annum.

South Shields, Ingham Infirmary and South Shields and Westoe Dispensary.—Senior House Surgeon. Salary £100 per annum, with residence, board, and washing.

Stockport Union, Stepping Hill Hospital.—Resident Assistant Medical Officer. Salary £130 per annum, with apartments, rations, &c.

Tunbridge Wells General Hospital.—House Surgeon, unmarried. Salary £100 per annum, with board, apartments, &c.

Victoria Hospital for Children, Tite-street, Chelsea, S.W.—Surgeon to Out patients.

Wallasey Dispensary and Victoria Central Hospital.—House Surgeon, unmarried. Salary £100 per annum, with apartments, board and service.

West Bromwich District Hospital.—Senior House Surgeon, unmarried. Salary £110 per annum, with, board residence, and laundry. Also Assistant House Surgeon, unmarried. Salary £75 per annum, with board, residence, and laundry.

West London Hospital, Hammersmith-road, W.—*Officer in Charge of X Ray Department.*

Western General Dispensary, Marylebone road, N.W.—*Senior* House Surgeon. Salary at rate of £100 per annum, with board, residence, and washing.

Worcester General Infirmary.—House Physician. Salary £80 per annum, with board, residence, and washing.

The Chief Inspector of Factories, Home Office, S.W., gives notice of vacancies as Certifying Surgeons under the Factory and Workshop Act at Whitchurch, in the county of Hants; at Henley-in-Arden, in the county of Warwick; at Stratton, in the county of Cornwall; and at Penarth, in the county of Glamorgan.

Births, Marriages, and Deaths.

BIRTHS.

Alcock.—On June 15th, at Downshire Hill, Hampstead, N.W., the wife of N. H. Alcock, M.D., of a daughter.

Brodie.—On June 13th, at Tetbury, Glos., the wife of Desborough Brodie, M.B., B.S., of a son.

Gervis.—On June 14th, at Hurdis House, Seaford, Sussex, the wife of Charles Berkeley Gervis, M.D., of a daughter.

Way.—On June 12th, at Kenilworth Lodge, Southsea, the wife of Montague Way, L.R.C.P. Lond., M.R.C.S. Eng., of a son.

MARRIAGES.

Groves—Miller.—On June 12th, at St. Mary's Church, Speenhamland, Newbury, Charles Nixon Groves, M.A., M.D. Oxon., to Frances Minnie, younger daughter of Frederick Montague Miller, J.P., M.R.C.S., L.R.C.P.

Joy—Angus.—On June 15th, at Independent Church, Brixton, S.W., George Percy Joy, M.A., M.B., Ch.B., to Jane Angus, eldest daughter of Alexander Angus of Aberdeen.

Macneill—*Graham.*—On June 14th, at the private chapel, Langholm, by the Rev. J. A. Seaton, Robert Archibald Macneill, M.B., Ch.B., Surbiton, Surrey, second son of John Macneill, National Bank House, Langholm, to Ida Doeg, younger daughter of Henry Graham Holmwood, Langholm.

Milward—Tilley.—On June 11th, at St. Augustine's Church, Edgbaston, by the Venerable Archdeacon of Birmingham, assisted by the Rev. H. R. Hall, rector of Boothby, Lincoln, Frederic Victor Milward, B.A., M.B., B.C. Cantab., F.R.C.S. Eng., son of the late Colonel Victor Milward, *formerly* M.P. for the South-Western Division of Warwickshire, and of Mrs. Milward, Tiddington, Stratford-on-Avon, to Elinor Mary (Nora) Tilley, eldest daughter of Ben B. Tilley of Cromartie, Edgbaston.

DEATHS.

Coates.—On June 16th, at The Hill, Laverstock, Salisbury, Harcourt Coates, M.R.C.S. Eng., L.R.C.P. Lond., aged 64 years.

Ley.—On June 16th, at his residence, 11, Longfield-road, Ealing, W., Henry Smith Ley, Captain Royal Navy (retired), the *dearly loved* husband of Sarah Ann Ley, and son of the late Commander George Ley, Royal Navy, of Rochester, Kent, in the 81st *year of his* age.

N.B.—A fee of 5s. is charged for the insertion of Notices of Births, Marriages, and Deaths.

Notes, Short Comments, and Answers to Correspondents.

BRITISH BIRDS.

We have received the first number of a publication called *British Birds*, of which the subtitle is An Illustrated Magazine devoted to the Birds on the British List. Mr. Howard Saunders contributes a paper on Additions to the List of British Birds since 1899. We are sorry to say that most of the birds therein mentioned *were identified* by being shot. In one instance, at least, the shooting appears to us to have been quite unnecessary—namely, p. 13. On Feb. 2nd, 1905, an adult male of this Alpine species (the snow-finch) was shot at Rye Harbour, Sussex, and shown in the flesh to Mr. M. J. Nicoll who was on the look-out for the bird, having noticed it among a large flock of skylarks the previous day. Having identified the bird why not let it alone? Mr. P. H. Bahr contributes a charming account of the osprey, illustrated by some beautiful reproductions of photographs obtained, we are sorry to say, in America, for this beautiful and interesting bird is reduced in these islands to a solitary pair or so. Mr. C. J. Whymper writes upon the position of the woodcock's ear. It is remarkable, for it is below and in front of the eye. Mr. Whymper says that he gathers that this fact is *not generally, if at all,* known. In this, however, he is mistaken. The magazine is interesting but we hope that it will be devoted to the preservation of rare birds and not to their "collection."

A NEGLECTED TEXT.

To the Editors of The Lancet.

Sirs,—When next Mr. John Pratt *engages in controversy on behalf* of Biblical authority for "the use of alcoholic beverages as medical *remedies*," he will be well advised to *neglect* the text which he has adduced in his letter of June 8th, for he might search the Scriptures diligently without discovering another petard to hoist himself with so effectually. The passage referred to runs thus: "It is not for kings, O Lemuel, it is not for kings to drink wine; nor for princes strong drink: lest they drink, and forget the law, and pervert the judgment of any of the afflicted. Give strong drink unto him that is ready to perish, and wine unto those that be of heavy hearts. Let him drink, and forget his poverty, and remember his misery no more."

Clearly this means that strong drink may indeed be given to the utterly wretched in order to induce oblivion (alcohol was probably the most effectual narcotic known at the time), but that those who have responsibilities which demand alertness of mind and a just discrimination should abstain. Having ruthlessly *torn* the passage in half and flung the prohibition to limbo your correspondent triumphantly produces *the other fragment* as an unanswerable proof of the truth of his contention and apparently proposes to hurl it in the *face of some* recalcitrant "members of a particular friendly society." I venture to predict that he will find himself no match for his opponents in textual warfare and such "methods of barbarism." Let him take his stand boldly by *common* sense (and the Higher Criticism if necessary!), not forgetting that there is an increasing *tendency* to regard the pronouncement of Lemuel's mother as uncommonly good advice and sound medicine.

I am Sirs, yours faithfully,

June 17th, 1907.

The Context.

X RAYS AND FIBROSIS OF THE OVARY.

To the Editors of The Lancet.

Sirs,—Can you inform me, in relation to the action of x rays in producing fibrosis of the ovaries and testicles, whether all the constituents of these organs are affected? In the case of the ovary is a premature menopause induced and is there any constitutional *effect similar to* that of ovariotomy—i.e., in temperament, &c.? What length or exposure is known to have caused *fibrosis?*

I am, Sirs, yours faithfully,

June 19th, 1907.

Kirros.

⁂ There is no positive *evidence* up *to the* present to show that the x rays can produce a premature menopause or sterility in the human female subject. From the fact, however, that atrophy of the ovary has been produced in small animals, such as the rabbit, and with much greater difficulty in the bitch, it would seem that the x rays have a selective action on the ovary, but that the success of the experiment is greatly dependent on the thickness of the tissues lying between the ovary and the surface exposed to the tube. Atrophy of the ovary in woman would seem to be impossible to *produce by* x rays from the fact that in experiments on the cadaver in which a radiometric pastille was placed over the ovary itself no change in the pastille was recorded after prolonged exposure.—Ed. L.

A MEDICAL MAN AND GOOD OPENINGS.

Our readers may remember that we have refused to assist Dr. F. F. Jay to get into communication with those of *our advertisers* who require to buy or to sell practices because we do not conceive that Dr. Jay is likely to prove a useful *intermediary. Dr. Jay* is now approaching our advertisers through a firm of agents and we recommend those of our readers who receive communications from him not to reply.

CYCLE SADDLES.

To the Editors of THE LANCET.

SIRS,—As a cyclist I have had trouble from perineal pressure and am anxious to find a saddle which will remove any difficulty and be a comfort in riding. Perhaps some of your readers who have suffered similarly can give me particulars of such a saddle and mention the tilt at which it should be placed to secure the best result. If they would do this they would confer a great favour on Yours faithfully,

June 15th, 1907. ALGEBRA.

THE ENGLISH EQUIVALENTS OF CUILLERÉE.

THE exact English equivalent of the French word "cuillerée" is often difficult to determine in reading French medical literature or on a continental journey. Cuillerée, a spoonful, is an ambiguous word, and frequently it is used without qualification. In the new Belgian Pharmacopœia it is stated that the term "cuillerée," standing alone, refers to the cuillerée à soupe or à bouche, the equivalent of the English tablespoon, and holding about 15 grammes of water. The cuillerée à café has a capacity of about four grammes of water and corresponds to the English teaspoon. The cuillerée à dessert is the English dessert-spoon and holds approximately 10 grammes of water.

THE SANITARY INSPECTORS' EXAMINATION BOARD.

THE following are the successful candidates in the examination for sanitary inspectors under the Public Health (London) Act, 1891, held in May, 1907:—Miss Clare Ballantyne (National Health Society), Miss Mabel Bhose (Royal Sanitary Institute), Mr. S. Bowers (King's College), Miss E. J. Charlesworth (National Health Society), Mr. A. E. Clutterbuck (Royal Sanitary Institute), Mr. E. S. Crook (Royal Sanitary Institute), Mr. J. Crowther (Royal Sanitary Institute), Miss Mary Davies (Royal Sanitary Institute), Miss D. Ebbetts (National Health Society), Mr. H. Hunkin (Royal Sanitary Institute), Mr. F. H. W. Large (in office), Miss M. Lowe (Royal Sanitary Institute), Mr. Duncan J. Menzies (King's College), Miss H. C. E. D. Ogston (National Health Society), Mr. A. Parsons (King's College), Miss C. J. Ryan (National Health Society), Mr. F. Savage (Royal Sanitary Institute), Mr. F. Seckerson (Royal Sanitary Institute), and Mr. C. H. Taylor (in office).

◆

R. H.—1. Authorities on infant-feeding are almost universally agreed that cow's milk appropriately modified is greatly superior to the commercially prepared infant-foods. It is only necessary in cases in which there is any difficulty in digesting fat to remove any of the cream from the milk previously to dilution. In other cases the milk should be diluted according to the age of the infant and a small quantity of cream and sugar-of-milk added. 2. The Soxhlet sterilising apparatus can be used conveniently for pasteurising. In the latter operation the temperature of the milk must be maintained at about 80° C. for 40 minutes. This can be done by a proper adjustment of the flame with the lid of the steriliser partly open. For accuracy a thermometer should be used. 3. A useful small book upon infant-feeding and rearing is one entitled "The Physiological Feeding of Infants," by G. Eric C. Pritchard, M.D. Oxon. (London: The Scientific Press. 1900. Price 1s.). If our correspondent wishes for larger works on the question he will find much material dealing with the subject in the works on "Pedriatrics," by T. M. Rotch, M.D. (London and Philadelphia: J. B. Lippincott Company. Price 25s.); and "The Diseases of Infancy and Childhood," by L. E. Holt, M.D. (London: Sidney Appleton. Price 25s.)

Mr. C. E. Richmond.—The General Medical Council is empowered to remove a practitioner's name from the Medical Register for matters connected with his address, by Section XIV. of the Medical Act of 1858.

ERRATUM.—In "Notes upon Health Resorts," at page 1668 of our last issue, the line "[FROM A SPECIAL CORRESPONDENT]," instead of following the general title, should have been inserted after the line "THE AUSTRIAN SPAS."

COMMUNICATIONS not noticed in our present issue will receive attention in our next.

METEOROLOGICAL READINGS.

During the week marked copies of the following newspapers have been received:—*Whitby Gazette, Burnley Gazette, Liverpool Daily Post, Sidmouth Herald, Warrington Guardian, Alloa Advertiser, Gravesend and Dartford Reporter, Dumfries and Galloway Courier and Herald, Birkenhead and Cheshire Advertiser, The Blackburn Times, Buxton Herald, Morning Leader, Belfast News Letter, Standard, Daily Telegraph, Daily Graphic, Daily Chronicle, Tribune, &c.*

EDITORIAL NOTICES.

IT is most important that communications relating to the Editorial business of THE LANCET should be addressed *exclusively* "TO THE EDITORS," and not in any case to any gentleman who may be supposed to be connected with the Editorial staff. It is urgently necessary that attention be given to this notice.

It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this office.

Lectures, original articles, and reports should be written on one side of the paper only, AND WHEN ACCOMPANIED BY BLOCKS IT IS REQUESTED THAT THE NAME OF THE AUTHOR, AND IF POSSIBLE OF THE ARTICLE, SHOULD BE WRITTEN ON THE BLOCKS TO FACILITATE IDENTIFICATION.

Letters, whether intended for insertion or for private information, must be authenticated by the names and addresses of their writers—not necessarily for publication.

We cannot prescribe or recommend practitioners.

Local papers containing reports or news paragraphs should be marked and addressed "To the Sub-Editor."

Letters relating to the publication, sale and advertising departments of THE LANCET *should be addressed "To the Manager."*

We cannot undertake to return MSS. not used.

MANAGER'S NOTICES.

TO SUBSCRIBERS.

WILL Subscribers please note that only those subscriptions which are sent direct to the Proprietors of THE LANCET at their Offices, 423, Strand, London, W.C., are dealt with by them? Subscriptions paid to London or to local newsagents (with none of whom have the Proprietors any connexion whatever) do not reach THE LANCET Offices, and consequently inquiries concerning missing copies, &c., should be sent to the Agent to whom the subscription is paid, and *not* to THE LANCET Offices.

Subscribers, by sending their subscriptions direct to THE LANCET Offices, will insure regularity in the despatch of their Journals and an earlier delivery than the majority of Agents are able to effect.

THE COLONIAL AND FOREIGN EDITION (printed on thin paper) is published in time to catch the weekly Friday mails to all parts of the world.

The rates of subscriptions, post free, either from THE LANCET Offices or from Agents, are:—

FOR THE UNITED KINGDOM.				TO THE COLONIES AND ABROAD.			
One Year	£1	12	6	One Year	£1	14	8
Six Months	0	16	3	Six Months	0	17	4
Three Months	0	8	2	Three Months	0	8	8

Subscriptions (which may commence at any time) are payable in advance. Cheques and Post Office Orders (crossed "London and Westminster Bank, Westminster Branch") should be made payable to the Manager, Mr. CHARLES GOOD, THE LANCET Offices, 423, Strand, London, W.C.

TO COLONIAL AND FOREIGN SUBSCRIBERS.

SUBSCRIBERS ABROAD ARE PARTICULARLY REQUESTED TO NOTE THE RATES OF SUBSCRIPTIONS GIVEN ABOVE. It has come to the knowledge of the Manager that in some cases higher rates are being charged, on the plea that the heavy weight of THE LANCET necessitates additional postage above the ordinary rate allowed for in the terms of subscriptions. Any demand for increased rates, on this or on any other ground, should be resisted. The Proprietors of THE LANCET have for many years paid, and continue to pay, the whole of the heavy cost of postage on overweight foreign issues; and Agents are authorised to collect, and generally do so collect, from the Proprietors the cost of such extra postage.

The Manager will be pleased to forward copies direct from the Offices to places abroad at the above rates, whatever be the weight of any of the copies so supplied. Address—THE MANAGER, THE LANCET OFFICES, 423, STRAND, LONDON, ENGLAND.

Communications, Letters, &c., have been received from—

The Croonian Lectures

ON

PLAGUE.

Delivered before the Royal College of Physicians of London on June 18th, 20th, 25th, and 27th, 1907,

BY W. J. R. SIMPSON, M.D. ABERD., F.R.C.P. LOND.,

PROFESSOR OF HYGIENE AT KING'S COLLEGE, LONDON; GOVERNMENT COMMISSIONER TO INQUIRE INTO CAUSES AND CONTINUANCE OF PLAGUE IN HONG-KONG, 1902, ETC.

LECTURE I.

Delivered on June 18th.

INTRODUCTION.

MR. PRESIDENT AND FELLOWS,—I esteem it a great honour to have been asked to deliver the Croonian lectures for this year and it is with a deep sense of responsibility that I undertake the duties. My predecessors in this important office have placed before the College the results of their scientific researches in anatomy, physiology, and pathology which have afterwards proved to be of the greatest practical value to the physician and surgeon in the domain of curative medicine. I am not in a position to follow in their footsteps, my province lying in another direction, and it would therefore be presumptuous on my part to attempt to throw light on my subject from that point of view. If I therefore depart from the usual course adopted in these lectures, with perhaps the exception of the late Sir John Burdon Sanderson who in 1891 lectured "On the Progress of Discovery Relating to the Origin and Nature of Infectious Diseases," it is because my work has been mainly concerned with the application of scientific medicine in its preventive aspects.

The subject I have selected for these lectures is plague. It is one which a few years ago could only have been treated from a historical point of view; now it is of intense interest, for it has suddenly become the most important epidemic disease of the present day. Plague has within ten and a half years caused in India over five million deaths, of which over four millions have occurred during the past five years. It is because of this mortality and because it is generally supposed, erroneously, I think, that so far as Europe is concerned plague is a disease of the past and will not prevail in epidemic form again, that I propose to lecture on this subject. I am further encouraged in doing so because the Royal College of Physicians has taken a very considerable interest in the recrudescence and development of plague, more particularly with reference to the great mortality it is producing in India, and has shown that interest by the deputation, headed by the President, which waited on the Secretary of State for India in July, 1905, representing to him the gravity of the situation in India.

DISCOVERY OF THE PLAGUE BACILLUS AND ITS RESULTS.

Plague is a very ancient disease but the *recent discovery* of the causal agent is so epoch-making that *it divides* its history into two distinct periods of very unequal length. The first period is that *previous to 1894*, before the discovery of the bacillus of plague by Kitasato and Yersin. The second covers the years which have elapsed since that discovery. One extends over several thousands of years at least; the other is only some 13 years old.

The fact that the specific bacillus is found in the buboes of the bubonic form, in the blood of the septicæmic variety, in the contents of the vesicles and *pustules* that sometimes appear on the skin, and in the sputum of pneumonic cases places the physician in a more favourable position for diagnosis of this disease than he ever was *before*. *It* provides him with a test, confirmatory or *otherwise*, of the suspicions he may have arrived at from the clinical symptoms of the disease and enables him to come to a conclusion with a degree of certainty which was previously impossible. It should also put an end in future to the controversies and discussions similar to those which invariably arose in former times when an epidemic threatened and which resulted in loss of valuable time before measures were taken to check the epidemic.

Smears from the contents of plague buboes or

pneumonic cases show usually on staining large nu bipolar microbes. In some cases, however, the micr few in number and in rare cases their presence is coverable by the microscope but only by culture and tion into susceptible animals. This is practically for the blood in septicæmic cases and also in bubor a short time before death. The typical plague bac their bipolar staining and ovoid shape are frequentl with others less typical having a great variety of fo cluding long and slender bacilli, and taking on the sta faintly. Spherical-like and disc forms may be foun buboes during life and in affected tissues after death. swollen and irregular-shaped bacteria do not stain their advanced stages and ultimately present only outline. The importance of these forms lies in the f they are prone to lead to mistakes unless the great va which the plague microbes may undergo are borne i Valuable as the morphological and staining charact of the plague bacilli are in times of plague, they ca wholly depended on to decide whether the first case unknown or suspected disease in a hitherto healthy are plague. Resort has then to be had to cultures in the case of plague give particularly trust results.

The *stalactite* growth in peptone broth which w covered by Haffkine is the surest culture test in other bacilli give a similar stalactite formation. drops of oil or butter fat may be added to the broth. In either medium kept in a condition of quietness the plague germs grow from the surface wards into the fluid in the form of stalactites. To the formation the flask has to be secured against the sl vibration and against sudden changes of tempe especially if applied to one side of the flask. In Lon the vicinity of the Underground Railway such are the tions that the stalactite formation is very difficult to If nutritive gelatin are used instead of broth and the is kept in the incubator at 35° C. the medium remai and the stalactite formation is more easily obtained particularly typical.

The involution forms which the plague bacilli ass dry agar are also very distinctive. They only app bacilli which have been recently removed from the of plague patients and are generally lost when the m has been cultivated for some time in the laboratory involution forms when quite typical are spheres and various sizes resembling yeast cells and are many larger than the bacilli themselves. They undergo changes according to the age of the culture. Norm first, they become slightly swollen and rounded; late size increases and they may reach in volume as much times that of the original bacillus. These forms at firs the stain well but subsequently portions of the cell more faintly. Later the whole cell refuses to stai ultimately there are seen only powder-like granules indi the position of the cell. In other cases the involution another form such as pear and crescent shapes and fila of unequal diameter.

A third characteristic is the appearance of the cult dry agar. When the plague bacillus is spread uniforml the surface of dry agar from which all condensation flu been evaporated the growth on culture is uniform possesses a peculiar appearance. When the tube is hel *horizontal* position with the growth downwards a examined through the depth of the agar by reflected li has the appearance of the sheen seen in the back looking-glass. Unless dry agar is taken this appearan not obtained, and instead of a shining uniform growth will be a layer of microbes of varying thickness and st over this growth will be colonies of different sizes sugge contamination by extraneous microbes. Inoculation o microbe into susceptible laboratory animals, such as guinea-pigs, and mice, furnishes an additional test in earlier cases.

The certainty of diagnosis which has thus been acquire the physician is of inestimable value on the first appear of suspicious cases in a community. Thus the public he authorities in this and other countries are able at onc *determine* whether a suspicious illness or death reporte them is plague or not and on the information so obtaine take immediately, if necessary, the requisite measure check the spread of the disease.

precision which was impossible before and many observations can now be confirmed by experiments. For instance, it is now absolutely proved that the epizootic of rats which has been observed so frequently as associated with plague epidemics is plague in rats. The relationship was formerly suspected, but now it is established. The isolation of the bacillus has also led to the discovery of Haffkine's prophylactic, the value of which as a preventive of plague is, as will be shown later, well established. Whether sufficient advantage has been taken of the new knowledge thus acquired will be considered afterwards.

It would be a mistake to suppose that because the present period has been so fruitful of results from a scientific and practical point of view that the past is sterile. On the contrary, it is full of observations of the highest importance, the value of which is only being slowly realised as greater experience in plague epidemics is gained. The clinical aspects of plague are as well described by the older authors as by the most recent, the mortality is as great to-day as formerly, the variation in the types of the disease was known, and the epizootic among rats and other animals, and the rôle which some of them play in the spread of the disease were recognised, although not proved to demonstration as now, and formed the bases of some of the preventive measures employed to check the disease. It will accordingly not be wasting time to refer briefly in this first lecture to some of the more salient facts connected with the history of plague. The antiquity of the disease, its endemic centres, its pandemics and epidemics, which are all so well described by Dr. J. F. Payne, a distinguished Fellow of this College, need not detain us.

THE PANDEMICS OF THE SIXTH AND FOURTEENTH CENTURIES.

Pandemics of great magnitude are fortunately few in number and far between. There have been several pandemics, but two only are recorded as standing out conspicuously as scourges of a particularly devastating character and the effects of which were felt for many years after they had disappeared. These were the Justinian pandemic in the sixth century and the Great Pestilence of the fourteenth century, later called the Black Death. The long interval of 800 years intervened between these two great pandemics of plague. Between them were many epidemics plague in Europe, Asia, and Africa, some of which assumed ore or less pandemic proportions, but none reached the dimensions of these two. The origin of neither is known, but in both great commercial centres played a prominent part in maintaining and distributing the infection. The Justinian plague, which continued over 50 years, first attracted attention by its outburst at Pelusium, which was then an emporium for the produce of the East and the West. The endemic centres of Mesopotamia, Arabia, and Æthiopa were in commercial relationship with Pelusium, and it is probable that the infection came from one of these. The balance of evidence is in favour of Æthiopa. It is a matter of interest to note that within recent years endemic centres of plague have been discovered in German East Africa and Uganda. The town in which plague reaches such dimensions as to attract more than local attention is seldom the one in which it originates. For instance, at the present day the pandemic now prevailing is commonly attributed to Hong-Kong and Canton, whereas the disease was brought to these cities from the Chinese endemic centre of Yunnan.

The great pandemic of the fourteenth century was also associated with large commercial centres, for it entered Europe by the important emporiums and marts situated at that period on the Volga and in the Crimea and which, as pointed out by Creighton, were the terminal marts of the northern caravans from China and the Far East. It should be mentioned, however, that they were also the marts connected with the trade routes from India. The origin of the pandemic has been ascribed to China and to India. The Russian records place its starting point in India. Clemow, in his recent work entitled "The Geography of Disease," points out that plague prevailed in India in 1332 and that probably the Russian chroniclers are correct. Wherever the pandemic arose there appears to have been for several years a wide diffusion of the disease in the large dominions belonging to the Tartars and the Turks who at that time ruled over the greater part of Asia. Galfridi le Baker Swynebroke set down the period of prevalence in Asia before plague entered Europe as seven years. When it did arrive it is estimated to have destroyed 25,000,000 of its inhabitants. England and Wales at the lowest computation lost 2,500,000 of its inhabitants, or about half of its total population.

For over 300 years after this visitation Europe suffered from fresh invasions of plague, which reinforced the languishing infections already existing from previous ones. In the countries attacked there were some epidemics in towns, which, though continuing only for a few months, are memorable for their great mortality. For instance, the epidemic in Venice in 1576 caused 70,000 deaths; that in Moscow in the same year, 200,000 deaths; that in Naples in 1656, 300,000 deaths; that in Rome in the same year, 145,000 deaths; that in Genoa, 60,000 deaths; and the epidemic in London in 1665, nearly 70,000 deaths. It was exceptional for an epidemic to recrudesce and occur year after year, which in India is almost the rule, so that in the latter case the mortality, though smaller in individual epidemics, gradually accumulates, with very few exceptions, to a proportion as great if not greater than that recorded in former times. Thus, for instance, in Poona, which is a town with a population of 120,000, over 40,000 of its inhabitants have died from plague in ten years, which is proportionally at least twice the mortality of the great plague of London in 1665. In Bombay over 150,000 of its inhabitants have been destroyed by plague. In this respect the history of plague tends to repeat itself. In the pandemic of the sixth century it is recorded that "if it passed over any place only slightly or mildly touching the inhabitants it returned there afterwards, leaving untouched the neighbours against whom it had spent its rage before, and it did not depart from there until it made up the full measure of the dead in proportion to the amount of destruction which it had brought on its neighbours."

THE EFFECT ON THE LIVING OF GREAT EPIDEMICS OF PLAGUE.

Great epidemics of plague not only destroy large numbers of people but they leave their traces on the living. The effects on the living have usually been very marked and very similar. They are mostly psychological and social in their nature. Great numbers of the living are unable to bear the strain of the scenes around them and the uncertainties of life which the epidemic brings too plainly before them. Minds which have hitherto been sober and calm become overwrought, unhinged, and hysterical. Excitability and suspicion are engendered, often leading to illusions, delusions, and excesses of all kinds, which in some instances become contagious and dangerous. The change is not sudden but comes gradually. First of all, the normal courage, solicitude for the sick, hope, and religious trust which belong to the healthy mind are unaffected, but later these are associated with intense pity, exaggerated religious fervour, and the deepest despair. Then they are followed by panic and a total revulsion of feeling in which the predominant features are fear, selfishness, callousness, and heartlessness, and later still, if the scourge continues, there is a display of all the most sordid and worst passions on the part of the unbalanced portion of the population.

Plague, above all disasters, tends to bring out for a time the weak points in humanity and seldom the virtues. Hecker gives an account of the frenzy and mania caused by the mental strain brought on by the terrible events associated with the Black Death. He describes the doings of the flagellants in Germany, Hungary, Poland, Bohemia, Silesia, and Flanders, who marched through the cities in well-organised processions and who bore triple scourges, tied in three or four knots, in which points of iron were fixed and with which they flogged themselves. Harmless and welcome at first they later became a terror to the inhabitants of every place they visited. He describes also the epidemic of dancing mania that followed and he gives an account of the cruel and fanatical persecution and wholesale massacre of the Jews who were accused of poisoning the wells and thus causing the plague. He says: "Already in the autumn of 1348 a dreadful panic caused by this supposed empoisonment seized all nations; in Germany especially the springs and wells were built over that nobody might drink of them or employ their contents for culinary purposes, and for a long time the inhabitants of numerous towns and villages used only river and rain water. ...... By this trying state of privation, distrust and suspicion, the hatred against the supposed poisoners became greatly increased and often broke out in popular commotions which only served still further to infuriate the wildest passions." The suspicion and rumours regarding the poisoning of the wells in the Punjab are only the reappearance of a part of the credulity and delusions which prevailed during the time of the Great Pestilence of the fourteenth century.

There were other effects besides these disorders of the mind. The whole social structure became seriously disorganised owing to vast tracts of country becoming waste land and an immense number of huts and houses becoming tenantless. Prices of commodities rose, rents fell, payment of the taxes on land could not be obtained. There were agrarian, labour, and political troubles. Labourers and workmen were scarce and demanded higher wages, and it was found impossible by laws, imprisonment, fines, or any other methods, to bring them to conform to the older order of things. A new era with a new spirit sprang into existence which in the course of years and after many struggles banished the old.

THE PERIODIC QUIESCENCE AND RECRUDESCENCE OF PLAGUE.

The epidemics of the East and West have generally been more or less synchronous with one another. The last pandemic of plague was in full activity in the seventeenth century and covered a large portion of Asia, Africa, and Europe, but towards the end of the century the disease began to contract its limits, leaving Western Europe free in the course of a few years, a freedom which, with one notable exception, has continued. That exception was the epidemic in 1720 in Marseilles, when 60,000 of its inhabitants died from plague which had been imported from the East. As regards the rest of Europe the retrocession continued, and in the course of 150 years plague not only disappeared from Europe altogether, but also showed a remarkable cessation in its old endemic centres of Mesopotamia and Arabia. What remained of the disease was shown by Tholozan to pass through a very definite stage of development, being mild at first, then virulent and again mild, and the preponderating element was mildness. The mild plague consisted of glandular swellings unaccompanied by fever, the swellings showing themselves in the groin, armpit, or neck. The epidemics which Tholozan studied were observed by him to be self-limiting in their extension and, as he points out, were not controlled by the plague measures which were often adopted after the plague outbreak had ceased. Within recent years the plague epidemics that arose from the old centres in Mesopotamia and Arabia were apparently incapable of wide extension and even under conditions seemingly most favourable for their spread. The conclusion from Tholozan's researches appeared to be that for epidemic plague endowed with qualities of diffusion, whatever that may mean, no quarantine on land would stop its progress, while for other epidemics of a self-limiting character quarantine on land was not required.

Following the retrocession and contraction of plague Europe has remained free for over 60 years, broken only by a short but virulent outbreak on the Volga in 1879, investigated by Dr. J. F. Payne and Surgeon-Major H. Colville; by a small outbreak at Oporto in 1899, and a few cases at Glasgow and Naples in 1900. Western Europe has been free for nearly 200 years, the last epidemic being at Marseilles nearly 187 years ago. The Great Plague of London occurred more than 240 years ago.

Quiescence of plague for varying periods is not a new feature in the history of the disease. It is necessary to emphasise this fact, for the long quiescence in Western Europe has given rise to the view that Europe has seen the last of its plague epidemics, and accordingly the epidemic now prevailing in India is viewed with regrettable complacency. I think this view of the invulnerability of Europe is as likely to be as correct as the prevalent notion that London was freed of plague by the Great Fire, irrespective of the fact that plague remained in London for 14 years after and that the disease disappeared from the whole of England and most of Western Europe about the same time.

Subsequently to the Justinian plague and its offshoots Europe, with the exception of an epidemic in Constantinople in 697 and another in Sicily, Calabria, and Constantinople in 749, remained free from plague for 400 years, and Syria, which is nearer the endemic centre of Mesopotamia, remained free for 200 years. Bagdad itself in the centre of the endemic area remained free for some 50 years at the commencement of the Abbasidic dynasty at a period of unexampled prosperity. Moreover, Egypt, which has suffered at varying intervals from devastating epidemics of plague during the past 2000 years, remained free from the disease from the eighth to the eleventh century, or a period of 300 years. Long immunity of towns as of countries is also not uncommon in regard to plague epidemics even when plague is in the country. When Bombay was attacked with plague in 1896 it had been free from the disease for 184 years, when Moscow was attacked in 1771 it had been free for 150 years, and when London was attacked in 1499 it had been free for 150 years.

Various explanations have been given of the retrocession of plague from Europe. It has been ascribed to the social and sanitary improvement of the people since the seventeenth century; it has recently been set down to the invasion of the Mus decumanus at the beginning of the seventeenth century and the retirement, except from the seaports, of the Mus rattus; and it has been attributed to the abandonment of overland routes as the principal means of transport and communication between the East and West, to the substitution of sea routes, and to the introduction of quarantine at seaports trading with infected countries. None of these explain in a satisfactory manner the sudden retrocession of plague which stands as a remarkable epidemiological fact, but individually and collectively they may have exercised an important influence in keeping the disease in check once it had receded. Probably the most powerful of these was the change of land routes to sea routes whereby the transport of goods from the East to Western Europe was no longer effected by caravans which passed through the endemic centres of plague in Mesopotamia and Arabia. It was a change which must have materially lessened the chances of infection and of importation of the disease. From this point of view the new railway schemes which are to link the East with the West and reopen the old overland trade routes are not unlikely, unless special precautions are taken, once more to bring with them the risks of plague importation.

THE GENERAL CLINICAL FEATURES OF PLAGUE.

Clinically, plague presents the same features to-day as those described by the most ancient writers on the subject. The accounts of the disease are remarkably alike whether given by Dioscorides and Posidonius in the third century before the Christian Era and referred to by Rufus a century later when writing of the plague prevailing in Lybia, Egypt, and Syria, or by Procopius in the sixth century, or by Guy de Chauliac in the fourteenth century, or by Skeyne in the sixteenth century, or by Diemerbroeck, Lodge, Hodges, or Boghurst in the seventeenth century, or by the numerous writers on plague since that time up to the most recent years.

The glandular swellings in the bubonic form, the coughing of blood in the pneumonic, the extreme prostration, pallor, muscular weakness, delirium and rapid death in the septicæmic, and the appearance of boils or blains in the carbuncular type have been observed and described in both ancient and modern epidemics of plague. Procopius graphically describes the sudden onset and fever, the appearance on the day of attack or the next day or a few days later of the bubo in the groin and armpit and sometimes in the neck, the drowsiness in some, the madness in others, the desire to wander, and the difficulty of keeping some patients in bed; he mentions the large size and suppuration of the bubo as indicating a milder attack and the reverse a severe and fatal illness and he draws attention to a feature which every physician soon learns for himself—viz., the uncertainty of prognosis. The patient's appearance is most deceptive and cannot be taken as a guide; patients pronounced to be getting well will not infrequently suddenly die and others in whom all hopes of recovery are abandoned recover with a rapidity that is marvellous. Procopius does not forget to record the comparative immunity of physicians and attendants.

The description by Guy de Chauliac of the epidemic of Avignon in 1348 is of special interest because it is written by a medical man of high standing in his day and because it distinguishes more clearly than others before him the pneumonic and bubonic forms of plague. Guy de Chauliac was himself attacked with plague towards the end of the epidemic but recovered. He says: "I felt a continued fever with a swelling in the groin and was ill more than six weeks in such great danger that all my friends thought I should die, but the swelling ripening under the treatment I have described, I escaped by the mercy of God." The treatment consisted in the application of figs and cooked onions mixed with plantains and butter, to ripen the swellings, followed by incisions and the usual treatment of open sores. Describing the epidemic he says: "The plague commenced in January, it continued seven months during which time it appeared in two forms. During the first two months it was accompanied by a continuous fever and with a coughing of blood. All who were attacked died in three days. During the other months the continuous fever was accompanied with tumours and boils which appeared on the external part of the body chiefly in the armpits and the groin. Those who were thus attacked died in five days. The disease was so severe and so contagious, especially that which was attended by coughing of blood, that it was contracted not only by visiting and living together with the sick, but by being in their presence, so that people died without service and attendants. Men were buried without priests and without religious rites, the father abandoned the son, and the son approached not the father. Charity was dead and every hope lost."

The very infectious character of pneumonic plague as distinguished from the other forms of the disease is now fully established, and it is the one form which is dangerous to medical men, nurses, and attendants on the sick. The sputum and blood coughed up teem with plague bacilli, as was first shown by Major L. F. Childe of the Indian Medical Service. Fortunately, most epidemics of plague partake more of the bubonic than the pneumonic variety, otherwise the liability to infection would be as great as it is in influenza.

VARIATION IN TYPE AND BEHAVIOUR OF DIFFERENT EPIDEMICS.

All epidemics are not alike, although their general characters are similar. The bubonic, pneumonic, septicæmic, and carbuncular varieties of the disease may vary much in their relative proportions in different epidemics, and symptoms may be present in some epidemics which are absent in others. The situation and relative position of the buboes may differ, and instead of being with the usual frequency in the groin, armpit, and neck may be found in the popliteal space, elbow, and other positions. In older epidemics carbuncles and tokens or petechiæ were observed, but they have been rare in later epidemics. In the epidemic of the sixth century affections of the throat and withering of the limbs and gangrene were added to the buboes, carbuncles, and black boils, or pustules; in the fourteenth century the pneumonic form was particularly prevalent; in the sixteenth and seventeenth centuries sweats were a distinct feature. In the plague of London there were coloured sweats. Hodges says: "These sweats also of the infected are not only profuse, but also variously coloured; in some of a citron hue, in others purple, in some green or black, and in others like blood. The sweat of some would be so fœtid and intolerable from a kind of empyreumatic disposition, possibly of the juices, that no one could endure his nose with the stench." Nothing of this kind has been recorded in recent epidemics, nor have the carbuncles which formed a very conspicuous and common feature in many epidemics been observed of late years with much frequency; when they have been observed the type of plague has generally been of a milder character. This mildness was also noticed in a number of the Egyptian epidemics contrasting much with other epidemics in which the carbuncles always signified a very fatal form of the disease. The comparative absence of nervous symptoms and septicæmic cases gave to the Cape Town epidemic a character differing in these respects from that of the Hong-Kong and Bombay epidemics which I saw. The Poona epidemic of 1906 also struck me as presenting fewer of the nervous disturbances which I witnessed there in the epidemic of 1897. It is noticeable that when the disease is comparatively mild views as to its non-contagiousness prevail, whereas when severity is its distinguishing feature contagion is in favour. Recent observations would indicate that both contagionists and non-contagionists were right to some extent, though their views were of the most opposite character. Pneumonic plague is directly infectious from man to man, the bubonic is not directly infectious, while the septicæmic may possibly be both directly and indirectly infectious. It would accordingly depend on the proportion of each of these varieties in an epidemic as to the contagiousness or the non-contagiousness from the disease being most predominant.

The great proportion of pneumonic cases in the epidemic of 1348 and the contagiousness of this form of the disease probably account for the rapidity which characterised its spread and which has recently been observed to be a marked feature in small local outbreaks of this form of the disease. If this pandemic be excepted together with a number of small local outbreaks of plague one of the peculiarities of plague is its slow progress from place to place, districts and towns close to those infected remaining for a long time free from the disease.

A frequently quoted instance is the Great Plague of London taking six months to travel from St. Giles's to Stepney. In Bombay the plague confined itself to the dock quarters before it spread to other districts. At Poona over six months elapsed before the disease established itself at Kirkee which was in daily communication with Poona and only separated by a river spanned by a bridge. During the first outbreak in Canton in 1894 in which 80,000 out of 1,000,000 inhabitants died from plague, the disease never crossed the narrow creek, some 20 yards wide, which separated plague-infected houses in the Chinese town from the European settlement of Shamien; neither Europeans nor the Chinese servants on the premises nor the rats in the foreign settlement were affected. The water here provided a check to the spread of the disease. It was also observed that the Chinese population living on the river did not suffer from the epidemic, which reminds one of a similar observation during the Great Plague of London. It is facts such as these and that animals living in the ground were affected by plague that gave rise to the view held by the Chinese and the older non-contagionists in Europe that plague was a soil disease and that the spread of it was due to miasmata from the ground. The discoveries of Manson and Ross have revolutionised our notions of miasmata, and from this new standpoint the miasmata of plague appear to be explained by the rôle which the rat and the flea play in the dissemination of the disease, but many links are wanting before a satisfactory explanation of the recrudescence of plague is available.

ANCIENT ASSOCIATION OF THE RAT WITH PLAGUE EPIDEMICS.

The association between plague and rats is a very old observation. Apart from scriptural references there is evidence derived from some of the ancient monuments and coins of the connexion being known. Apollo and Æsculapius are each represented with the rat at their feet. There was the famous statue of Apollo by Skopias in which the god has a rat at his feet. Snakes are destroyers of rats, and in Asia Minor and elsewhere before the advent of the cat harmless snakes were kept in houses and in the temples doubtless for that purpose. This practice probably explains the accounts so frequently given of snakes and serpents dying during epidemics of plague. Both the cat and the snake were venerated for their services to man.

There is an interesting coin brought to my notice by Dr. Sambon and which can be seen in the collection of colonial Roman coins in the British Museum (Fig. 1). It is a coin of the Emperor Lucius Verus struck at Pergamum in Asia Minor during a plague epidemic and represents Æsculapius with a rat at his feet and a small human figure standing by with his arms outstretched in the attitude of fear or worship. In the same collection there is a medallion of the Emperor Antoninus struck in commemoration of the erection of a temple to Æsculapius on the Tiberine Island at Rome. Plague was epidemic in Rome and a mission was sent to the temple of Æsculapius at Epidaurus to ask for advice. The advice given by the Æsculapian priests was apparently to destroy the rats, for on the reverse side of the coin is the return of the mission with a serpent, being welcomed by the river god (Fig. 2).

The dissemination of plague by domestic animals was formerly recognised even more than it is at the present day and very decided views were held, particularly regarding those animals in close association with man; not only rats but also dogs, fowls, and pigs were held to be agents in spreading the disease. When plague prevailed in Europe these animals were as much inmates of the house as the people themselves and it was observed, as it is in South-Western China to-day where the same conditions prevail, that during epidemics of plague the rats, fowls, pigs, and cattle sickened or died, which was attributed to plague. In the pandemic of 1348 it is recorded by numerous observers that dogs, cats, fowls, cattle, and rats died from the disease. Skeyne in 1568, in his work on the pest, states that "quhan the domestical foules become pestilential it is ane sign of maist dangerous pest to follow." The observations became so general that they formed a basis for certain orders in regard to the suppression of plague.

Every European country has in its old orders concerning the checking of plague epidemics instructions to the inhabitants under certain penalties to kill domestic animals or to keep them confined to the house. Creighton mentions some of these orders as bearing on the regulations in England and Scotland against the spread of plague.

In the regulations in London against the plague in the seventeenth century it is ordered that no hogs, dogs, pigeons, or conies shall be suffered to be kept within any part of the City. In Rouen on April 14th, 1407, it was ordered under penalty that no person of any condition or rank should keep pigs. When plague broke out again in 1498 a similar order was issued, and in 1566 the priests of the Madeleine and Commander of St. Antoine were forbidden to keep in their houses pigs, fowls, and rabbits. At Evereux in Normandy a police order was issued in 1561 that every one of whatever quality or rank should not keep pigeons, fowls, rabbits, and pigs under penalty of confiscation and a fine of ten livres, and anyone giving information would receive half the fine. The killing of dogs is in nearly every order. A photograph, kindly lent to me by Mr. Henry Wellcome, of a painting in the archives of Bologna representing a plague epidemic in that town is interesting, as it illustrates the actual killing of dogs during the epidemic. The picture shows the magistrate and his officers on duty. Some of them are removing the dead which are being lowered from the windows of the infected houses; priests are also to be seen administering the Sacrament. In the foreground are some men killing a dog and a little farther back there is a dog transfixed with an arrow Similar measures for controlling plague were taken a· Palermo in 1575. Ingrassia says, "an excellent measure was proposed and carried out. All dogs, cats, and other animals that might convey the plague from one house to another were to be destroyed." Not only were the dogs of the town destroyed but all those within a radius of at least four miles. Fiochetto, describing the measures that should be taken in the event of the discovery of an infected person in any house, says "fifthly, having killed all cats, dogs, fowls, and pigeons prepare arsenic for the rats." No mention is made of fleas on these animals but it is evident that experience had taught the authorities that these animals sometimes by contracting the disease and sometimes by carrying the infection on their coats, furs, and feathers, though not infected themselves, conveyed plague. In connexion with the conveyance of the infection by animals not suffering from the disease there is the observation made by the Austrian Commission in 1897 of plague bacilli appearing in the fæces of a dog fed with plague material.

The Cavendish Lecture

ON

THE CONSERVATIVE SURGERY OF THE ABDOMEN,

ESPECIALLY OF THE APPENDIX VERMIFORMIS AND ITS RELATION TO THE SURGICAL TREATMENT OF CHRONIC CONSTIPATION.

Delivered before the West London Medico-Chirurgical Society on June 21st, 1907,

BY C. R. B. KEETLEY, F.R.C.S. ENG.,

SENIOR SURGEON TO THE WEST LONDON HOSPITAL.

MR. PRESIDENT AND GENTLEMEN,—Set addresses and annual lectures are often so tedious that the question arises would not they be improved by a musical accompaniment. In a fine opera the dulness of the libretto is never observed until it is read at home without the singing and the orchestra. Therefore, well set to music a lecture's defects might wholly escape discovery. Original airs would be no more necessary during a Cavendish lecture than during a dance upon a tight-rope, which indeed it resembles when the lecturer trips along the edge of some great question upon which professional opinion is divided and is careful not to incline too much to one side or the other. I should ask my accompanist to begin with the Grenadier's song from *Iolanthe*—

> "I often think its comical,
> That every boy and every gal
> That's born into this world alive
> Is either a little Liberal
> Or else a little Conservative."

The average surgeon is less narrow-minded than the average politician; still we have among us men who seem to hasten to cut off, or to cut out, organs for insufficient reasons and others who imperil life unjustifiably in the endeavour to save limbs. Nay, our own consciences may have reproached ourselves for erring at one time in one direction and at another time in the reverse. Therefore, when I appeal to you this evening to take with me a short step or two in the direction of conservative surgery I am not so foolish as to regard myself as a Peter the Hermit or a Martin Luther preaching a crusade or a reformation. Never is it more desirable to be modest and cautious than when coming to a decision on the question whether it is better for a given patient to save an organ or to sacrifice it. Then, if ever, is the time to "gang warily." A greater dramatist than Gilbert made Portia say—

> "The quality of mercy is not strained,
> It droppeth as the gentle rain from Heaven."

Think of those ungentle and incautious surgeons who denounced the early ovariotomists as criminals. From them it was the quality of mercy descending, not as the gentle rain in season but like some ill-timed hailstorm, crashing down among the cornfields of July or, rather, among the blossoms of May.

There are still medical men who rarely fail to oppose or to delay fatally any radical surgical procedure that it may be in their power to obstruct. They plume themselves and sometimes go about telling some boastful tale of a limb saved, while forgetting the lives they have caused to be lost or spent in distress. However, what we are concerned with practically are not the early ovariotomists but the later ones, our own contemporaries. Are they not a little too ready to remove the internal organs of generation? Occasionally, as a general surgeon, I meet with patients who have had one or both ovaries removed for abdominal pain, which the sequel proves to have in all probability originated in quite a different part of the abdomen; then there is the practice of removing, as it were to complete an ovariotomy, the second ovary, lest it should afterwards be diseased. It is almost impossible for the second ovary to attain such a high standard of health and perfection as to ensure escaping from some operators. It must especially be careful not to be well developed. This spring I was consulted by a patient whose second ovary had been spared because it had the appearance of being atrophied and functionless. It afterwards enabled this lady to bear her first and only child—a healthy boy. Having due regard to the present state of abdominal surgery, surely, in a woman of child-bearing age, no ovary should be removed as a mere precaution against the risk of innocent ovarian tumour, because the patient can be watched and operated on early and safely if disease should actually appear, and in the meantime she can have the various advantages, not confined to fertility, of possessing an ovary.

We doctors not only have among us conservatives and liberals, but, to extend the analogy, we occasionally have outbursts of "unctuous rectitude." One of these a few years ago revolutionised a well-known hospital for women. After falling heavily on the innocent and nearly allowing some of the guilty to escape, it appears to have had the final result of deflecting surgical energy from the ovaries and tubes to the uterus. It is with great diffidence, and knowing well that I am not entitled to speak with authority on the point, that I would ask whether some cases of uterine fibroids in which hysterectomy is now performed could not be dealt with by enucleation of the growths. I am not referring to pedunculated or to purely subserous fibroids but to interstitial ones. The great mass of this kind of surgery goes, of course, to those who specialise, but a little of it occasionally comes my way accidentally owing to uncertain or mistaken diagnosis. Now, the chief objections to enucleation are, I suppose, the dangers of hæmorrhage and of sepsis. The practice of enucleating thyroid tumours gives an admirable training in dealing with bleeding in these cases and the open surgery of dislocations of the hip and shoulder points out the way to preserve asepsis in large, deep, complicated wounds. The case should be carefully selected and every preparation ready for hysterectomy be made. The uterus should be placed outside the abdomen during operation. As many fibroids as possible should be enucleated through the same superficial uterine incision, the finger or a blunt instrument being preferred when uterine tissue has to be divided, bleeding during operation prevented mainly by pressure with swabs and gauze packs, and finally also by a few catgut sutures round some of the uterine tissue. This gauze packing properly arranged protects alike against sepsis and recurrent hæmorrhage. The uterus should not be replaced in the abdomen until all bleeding has ceased and should be carefully inspected when inside. Of course, one end of each gauze pack is brought outside. It would be most desirable that both surgeon and assistants should have had previous experience in similar modes of operating in a less dangerous class of cases.

The appendix vermiformis is very near anatomically to the right ovary and Fallopian tube. In February, 1888, Treves read a paper before the Royal Medical and Chirurgical Society in which he described his first operation on this organ. To quote his own words: "In 1886 a patient with relapsing typhlitis came under my care at the London Hospital and after due consideration I proposed to 'deliberately seek for and remove his appendix.' I operated on him during a period of apparent health on Feb. 16th, 1887, and was able to correct the distortion of the appendix without removing it." The case is given at length in the Transactions of the Royal Medical and Chirurgical Society (vol. lxxi, p. 170 *et seq.*) and forms part of an epoch-making paper in which the whole subject of the surgery of appendicitis is briefly, but sufficiently and soundly, reviewed, and what is now known as the "interval operation" justified and recommended. My quotation is taken, for the sake of brevity, from a letter of Treves's to which I refrain from giving the reference, as it is unjust both to his own paper and to the Americans, to whom the surgery of the appendix probably owes more than to Europeans. The letter contains misplaced irony. I shall not be thanked for this defence. Too much sarcasm is a common fault of writers on the appendix. I myself avoid irony, which is to literature what the ostrich feather is to dress. A nodding plume is at once aggressive and attractive. Rightly worn it is a deadly weapon in the armament of the fair; but go to Whitechapel or Hammersmith on a Sunday and see the disastrous effect of putting it on the wrong way and dyeing it red, blue, and yellow.

In 1885 Charters Symonds had cut down upon the appendix and removed a fæcal concretion without excising the appendix.

Thus in the earliest two "interval operations" the appendix was left in the peritoneal cavity (walled off by adhesions in Symonds's case). Treves is, of course, a "London" and Symonds a "Guy's" man. If we think also of Mahomed, of Wilks, of Addison, and of Bright, it must be acknowledged that the insight into diseases of the appendix shown by Guy's men has been remarkable. They have always been before their time. But this mode of operating immediately gave way to appendicectomy. I ask you now to reconsider this matter.

Appendicitis is so dangerous not from the nature of the appendix but because of its position being intraperitoneal. No scruple was felt about amputating the appendix, because it was regarded as a useless structure—"an organic anachronism" Treves called it. But in 1904 Macewen[1] disputed this view and related interesting direct observations which he had been able to make on the functions of the appendix in a case of injury in which its orifice has been exposed to sight. Further, Weir[2] by his first operation of appendicostomy demonstrated that the appendix can be put to a surgical use. I myself had pointed out the possible surgical value of the appendix.[3]

What inference is to be drawn? Why, that when about to amputate a given appendix we should ask ourselves whether, in that particular case, it would not be better to preserve it, reverting to the original operations of Symonds and of Treves, but modifying them considerably, so as to give to them a safety and sufficiency which those original operations certainly did not possess. How is this safety to be given? The answer is by transferring the appendix from the peritoneal cavity and imbedding it in the abdominal wall, and by opening or amputating its distal end if its lumen is anywhere narrowed by stricture or other cause. I mean not a mere appendicostomy in which all but the stump of the organ is cut off, but the preservation and transference of the whole or of a great part of the appendix.

What cases are suited for this parietal transplantation of the appendix? 1. The healthy appendix in some cases of colitis, and in some of doubtful nature. 2. Appendices of which a fair length of the proximal part is free from stricture, kink, ulceration, and perforation, or which can be opened towards the distal end and cured of their defects.

The following cases are more or less unsuited: 1. Obliterated appendices. 2. Tuberculous, actinomycotic, and cancerous appendices. 3. Appendices which are gangrenous or perforated near the proximal end. 4. Appendices of which the base cannot be brought up to the parietal peritoneum without undue tension. 5. Those of which the meso-appendix is not long enough to permit them to be sufficiently straightened out or to be brought into the abdominal wall without dangerously interfering with their blood-supply. 6. Appendices which cannot be placed in good position in the abdominal wall without interfering with such drainage as the case may require. An extremely thick and fat meso-appendix is unfavourable but not an absolute contra-indication. In order to bring the base of the appendix up to the abdominal wall without tension it might be justifiable in some cases to free the attachments of the cæcum a little, but with due care of its blood-supply.

To take care of the main artery running to the appendix is an important point, to which I have to thank my friend Mr. L. B. Rawling for calling my special attention. In my own early appendicostomies I was protected from gangrene chiefly by good luck, as the only special precaution I took was to suture the base of the meso-appendix to the parietal peritoneum by a loose loop which did not strangulate the artery. Sometimes the appendix receives two arteries, one running near the cæcum supplying, say, the proximal fifth of the organ; but usually there is only one artery—viz., that which runs along or near the free margin of the meso-appendix. In all cases, therefore, except when a very short length indeed of the appendix is to be preserved in an ordinary appendicostomy performed on a person with a thin abdominal wall, great care should be taken not to strangulate the main appendical artery. If the base of the meso-appendix is very wide it may be button-holed and the edge of the parietal peritoneum and deep fascia united through the button-hole so as to make the appendix and its artery emerge at separate openings. I have found this quite practicable. Mere recent inflammation, or even such chronic inflammation and thickenings as are sometimes associated with mucous colitis are not contra-indications to parietal transplantation with appendicostomy.

[1] THE LANCET, Oct. 8th, 1904, p. 995.

[2] New York Medical Record, August 9th, 1902, p. 201.

[3] Brit. Med. Jour., 1894, vol. ii., p. 1112.

Between what layers of the abdominal wall should the appendix be placed? I have tried various positions and prefer now to bring it through the deep muscles nearly opposite the aperture in the peritoneum, then through the aponeurosis of the external oblique close to, but not exactly over, that aperture, and finally to place the greater part of the organ on the surface of the external oblique beneath the fat and superficial fascia. Of course, with much subcutaneous fat the appendix must be placed obliquely to reach the incision in the skin. So far I have observed no sign of hernia in any of my cases, not even in patients with thick, fatty meso-appendices for which room had to be found. All have had a fairly long stay in bed, usually a month after operation, but I have had two or three up in the third week.

Closely related with the question of preserving the appendix is that of—

THE SURGICAL TREATMENT OF CHRONIC CONSTIPATION,

for which parts and their functions have been sacrificed to a remarkable extent. The treatment of chronic constipation by anastomosing the lower end of the ileum with the sigmoid flexure is Mr. C. W. Mansell Moullin's. His case is described in the Transactions of the Medical Society for 1901, p. 199. When writing a letter to THE LANCET in 1903 describing a case of chronic constipation in which I had suggested exactly the same treatment to a patient of Dr. Daniel Lehane's and Dr. W. Bezly Thorne's, I overlooked Mr. Moullin's case and now apologise to him. I had read the correspondence between him and Mr. Arbuthnot Lane about the case and had been misled by it. In that Mr. Arbuthnot Lane described his first operation reported in THE LANCET of Jan. 17th, 1903, p. 153, as being for "a comparatively common, simple, definite condition of mechanical obstruction." Short-circuiting the intestine for mechanical obstruction had been performed before then by other surgeons—e.g., Dr. O. Gilbert B. Kempe, probably by many other surgeons, including myself. So that when Mr. Moullin wrote that his case was similar to Mr. Arbuthnot Lane's he did himself an injustice and unintentionally misled me.

But it is impossible to dissociate the subject of the surgical treatment of constipation from Mr. Arbuthnot Lane, who, though not the pioneer, is at all events the apostle of it and a brilliant teacher, and from Arbuthnot Lane and from other sources I think we can gather enough to satisfy us that the operation of short-circuiting is not really a satisfactory one for constipation. Arbuthnot Lane says himself that "if the patient is careless and does not attend to the daily evacuation of the rectum, material may occasionally pass backwards into the cæcum and hard masses of fæcal matter may rest there and perhaps cause irritation."[4] "May occasionally!" It would be more correct to say "must frequently," because the fluid contents of the ileum flowing into the rectum are practically an enema and an enema does not need to be very large to ascend to the cæcum. This is constantly seen in cases of cæcal fistula. And patients are careless. Is there a more constipated class than that of female domestic servants or a more careless one? Voyagers to the "coast of Bohemia" in the "eighties" will remember the late John Edward Soden's recitation of "Eastbourne" wherein a bather emerging from the rather chalky waters of that charming town is baked by a hot sun into a plaster cast and mistaken for a statue by Phydias:—

"I thought of the careless housemaid
And was frightened out of my wits,
Who would come with her broom in the morning
And knock off my pointed bits."

—Mr. Arbuthnot Lane goes on to say that the hard masses irritating the cæcum are removed as a rule, easily by an enema, but that "if the condition recurs" he removes "the cæcum and ascending colon up to the flexure," but that "the ideal primary operation would be the removal of the large bowel down to the junction with the ileum." If this were to be taken literally, it would mean that the ileo-cæcal valve would be an ideal anus. Of course, the inspiration of this idea of removing the whole of the large bowel comes from Metchnikoff, and a very good source too.

Let us grant that the great Parisian histologist is very likely right and that what we regard as inevitable old age is really produced by the action of the bacteria of the large intestine, does it follow from that that the colon should be excised? There are other alternatives—e.g., there is Professor Metchnikoff's own plan of a particular diet inimical to the bacteria which do the mischief; there is appendicostomy which enables the whole large intestine to be washed out through and through as much and as often as the patient or his medical attendant likes; and, finally, there is a question which I should like to put, though I suspect many will give it a quick and contemptuous answer in the negative. Is it not possible to keep the human colon throughout life in a state of freedom from pathogenic bacteria approximating to that which exists at birth and for a short time afterwards? These bacteria are certainly introduced from without. It is natural to say that their entrance is inevitable. But no serious attempts commencing in early infancy have been made to prevent it, at least none which can be compared to the trouble which a surgeon takes to keep bacteria out of wounds, trouble which practice makes a pleasure or causes to be taken without any sense of effort. On the contrary, the neglect of every likely means of keeping bacteria out of the alimentary canal is almost universal. Uncleaned or only half cleaned are the mother's nipples, the baby's lips and nose, its rubber teat, the thumb it sucks, the coral ring it bites when teething. Its first teeth when they come are neglected because they are its *first teeth*. Then, throughout life, no attempt is made to secure anything like sterilisation of all the food, solid and liquid. He who suggests such an attempt is met by satire, especially from those jovial journalists who think human happiness is inseparable from dirt and neglect, pleasant society unattainable without beer, peace of mind without tobacco. Or he is told that the bacillus coli may really be a beneficent organism which breaks up some constituent of the fæces, such as fibres which have not been torn by the teeth and might not easily get through an anus which would pass comfortably a Murphy's button or a tenpenny nail.

In the *Hospital* of May 11th of this year it is reported that Mr. W. Arbuthnot Lane showed at Guy's on April 28th 11 patients (10 females and one male) on whom he had short-circuited the intestine as a treatment of *chronic constipation*, "so as to put the large intestine altogether out of action," the reporter adds. But I am sure Mr. Arbuthnot Lane never said that. The patients themselves said that previous to the operation they had suffered from wasting and from incapacitating pain and that since they had regained health and strength and were able to take their ordinary food and suffered from no inconvenience. In some instances the operation had been performed three years ago.

Now, if these were cases of genuine mechanical obstruction there is not much to say against the treatment and there need be no surprise at the results. But in the vast majority of the cases of chronic and obstinate constipation there is either no mechanical obstruction at all, or if there is any it is at the pylorus or even in the small intestine. Further, we ought to have a precise and sufficient, if brief, report of each case. Was, for example, the condition of the appendix vermiformis always carefully noted? If it was not healthy perhaps an equally good result might have been obtained from ordinary appendicectomy. It must be remembered that Mr. Arbuthnot Lane regards appendicitis when not caused by a foreign body as a mere incident of chronic constipation and as a matter of fact there is a history of constipation "immediately preceding the attack" in 43 per cent. of cases of appendicitis.[5] Now the whole includes the part, so that if the cæcum and half the rest of the colon are excised the appendix comes out with them. Further, the population of the British Islands is about 40,000,000, of whom 0·1 per cent. are medical men, and many educated laymen see a medical journal now and then, so that in the minds of 40,000 medical men and an unknown, but large, number of the laity Mr. Arbuthnot Lane's name is inseparably linked with the idea of the surgical treatment of constipation. In these circumstances 11 patients were not a very large number to show at Guy's.

After being first rather taken with the idea of performing ileo-sigmoidostomy for obstinate constipation the more I reflected on it the less I liked it. There was a certain amount of experience to draw conclusions from. Cases had been recorded of ileo-sigmoidostomy for the relief of other conditions and experiments on animals had also been made. Moynihan sums up the inference to be drawn as follows: "Unilateral exclusion ...... in the large intestine does not prevent, at any rate for more than a short period, the backward flow of fæcal matter."[6] It may be said that when with an ileo-sigmoidostomy the ileum is cut in two the whole colon is converted into a long cæcum—not an improved condition, although I do not agree with the practice of calling the cæcum a cesspool. What analogy can there be between a cesspool and a rounded contractile bag with an aperture to empty it of a diameter nearly equal to its own, a bag which is alive, which is lined with secreting epithelium, endowed with a muscular wall, compressed by the muscles of the abdominal parietes, and nearly always found when examined to be full, not of fæces, but of gas?

---

[4] THE LANCET, Dec. 17th, 1904, p. 1699.

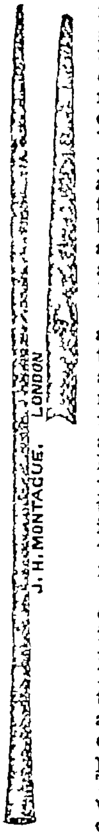
[5] Howard Kelly and E. Hurdon, p. 350.

And with regard to the real or supposed harmlessness of removing half the colon or more several thoughts present themselves. It is true that nutrition may be well preserved when no less than 17 feet of small intestine or even three-fourths of the liver are excised, but such facts do not settle the question. All maiming operations of the kind deprive the subject of reserve capacity of which he may one day be in need. The whole power of the large intestine to absorb fluid seems to be necessary to save the lives of some acute cases and of some patients just submitted to severe operations. A man may not miss one kidney, but that can only be so long as the other acts fairly well. And great as has been the advance of surgery it has not entirely abolished the dangers of more or less prolonged abdominal operations.

Sir William Macewen has a long paragraph referring very amusingly to the man of the future when completed by the surgeon—i.e., when deprived of his prepuce, his tonsil, his pharyngeal tonsil, his appendix vermiformis, his superfluous intestinal loops, his stomach, and his teeth, and when final arrangements are made for nourishing him with pellets of concentrated essences, sent out daily by manufacturing chemists and delivered by the local postman. I regret that we have here more irony. That one might think inseparable from disquisitions on the appendix if one reads only Treves, Lane, and Macewen, but one would be mistaken. There are Mayo Robson and Battle, one from Yorkshire, the other from Lincolnshire, where the people are very modest, and there is Lockwood, another Yorkshireman, with a gift of sarcasm, but who makes little public use of it. There are Tubby, Eccles, and Corner whose vast output of work leaves them no time "to deceive the world with ornament" or with irony, and there are many serious foreign and American authors. I have been greatly indebted to one of them, Howard Kelly, for references. Still the power of the appendix vermiformis to excite the spirit of sarcasm in men of genius is wonderful. One may see it in the daily press frequently. Genius must be allowed to have its way, even in such extreme cases as that of Baudelaire the French poet, for example. He did not excise the colon or shake the red plume of irony at all and sundry, but he kept a black mistress and dyed his hair green. One may admire without imitating. For myself, I sometimes excise part of the colon, though not for constipation. When I dissent from the views of other surgeons it is with great humility. I avoid irony and I do not dye the remains of my hair green.

I would suggest that the present and practical treatment for those cases of constipation and of bacterial infection of the large intestine which are grave enough to appeal to surgery is appendicostomy. I have now performed this operation 16 times, nine times in hospital and seven in private (with Dr. James Crombie, Dr. J. A. Shaw-Mackenzie, Dr. E. G. Younger, Mr. J. D. Roberts, Dr. A. L. Curtis and Dr. T. W. Bailey, Dr. E. A. Saunders, and Dr. Gilbert Richardson a case each). In the last the appendix had not been opened but merely placed in position, to be used if necessary after excision of the lower end of the ileum for tubercle, so that if not used it will not count.

In nine of the 16 cases the chief trouble was chronic constipation, in some of them amounting to complete obstruction at the time of operation. In most the constipation had existed for many years; in one it had been lifelong. The length of time some of them had gone without a motion was remarkable. In Dr. James Crombie's case it was to be counted in months; in Dr. Seymour Taylor's, a hospital patient, which was my first case, three weeks, and she was only 17 years old. Their ages ranged up to 76 years. One case of acute suppurative peritonitis died in consequence of the prostration which induced me to inject neutral saline through the appendix and two cases of cancer died ultimately, but in no case did either death or any apparent danger result from the appendicostomy. A middle-aged man came into the hospital with gangrene of the whole gall-bladder and an abscess extending down to the right iliac fossa. I found the appendix obliterated and did a cæcostomy for purposes of nutrition (vomiting had been persistent), but he died. I also performed a cæcostomy after Witzel's method in an obstinately constipated young woman who a year before had had removed an appendix containing fæcal concretions. At the former operation it would probably have been better simply to have removed the concretions and preserved the appendix, placing it in the abdominal wall ready for an appendicostomy. I am about to publish the cases.



Now in every one of the constipation cases the appendicostomy answered its purpose. In some the daily injection of hot water suffices. In most a certain amount of sulphate of soda or of magnesia has to be added. The quantity needed has tended to diminish rather than to increase. There are some drawbacks. Nearly all the cases still keep the appendix open. Unless the catheter is passed regularly, the opening tightens up until the patient has to come to the surgeon to dilate it. I have found the dilatation easy, even when the catheter has not been passed for a week or more and the opening has seemed all but closed.

An appendicostomy properly performed is a clean opening, not giving egress to fæces. And it is a very small opening so that the patient has to use a special catheter such as that made by Mr. Montague of Bond-street and kindly shown to-night by Messrs. Krohne and Sesemann An appendicostomy for constipation which required a catheter to be left in it I should regard as a comparative failure. Mr. Roberts's patient, who is 76 years of age, wishes to know if her opening which was made for acute obstruction may be closed. I advise her no. If there be anything in Metchnikoff's views her open appendix may help her to become a centenarian, not to say a multi-centenarian. She is quite bright enough and young looking enough for her age.

I had intended when I began the preparation of this lecture to make it cover a much wider field so that there might be something in it likely to interest everybody. I should have liked in particular to refer to the kidney, of which not an ounce should be removed if there is a good prospect of its being restored to health and usefulness and to sarcomata in the excision of which there is great room for thought and care However, I am grateful for the patience you have already shown. Patience is the quality most required in attempting to preserve parts and their functions. But has not someone said genius is patience? I ought to fear, therefore, that you may receive my remarks with the irony which I so deprecate, but that I feel sure of receiving from you the same kindness, friendliness, and indulgence with which our society has treated me for 25 years—i.e., for the best part of my working life, which has been so much associated with it and which you have now honoured by the invitation to deliver the Cavendish lecture.

A STANDING SCOURGE.—Mr. Fontana, British Consul in the coast district of Benghazy, Tripoli, observes, in his report for the year 1906, that there are upwards of 300 British subjects and British-protected persons in the district. The public health for several years has been very good, no serious epidemic having occurred. "Ophthalmia, however, is a standing scourge, and counts its victims by thousands, and even by tens of thousands, among the children. Among the Arab population of the town, families of which two or three of the members are blind are by no means rare."

---

[6] THE LANCET, Oct. 8th, 1904, p 1012.

THE INFLUENCE OF SCHOOL LIFE ON THE SPREAD OF SCARLET FEVER.

BY B. K. GOLDSMITH, M.B., CH.B. EDIN., D.P.H.,
ASSISTANT TO THE MEDICAL OFFICER OF HEALTH OF MANCHESTER.

THIS inquiry was undertaken at the request of the medical officer of health of Manchester, and the information on which the investigation is based is obtained from the reports made to the medical officer of health on every case of scarlet fever notified in the city of Manchester.

The total number of cases involved is 19,219. I have divided these into three groups of age periods—a division similar to that adopted by Sir Shirley Murphy in his report to the London County Council for 1894. These three groups are: (1) infants (ages 0–3 years), (2) school children (ages 3–13 years), and (3) adults (ages 13 years and onwards). In order that any inference drawn from the figures might be reasonably accurate the investigation was conducted in two parts, so permitting of comparison. Part I. deals with the years 1900, 1901, 1902, 1903, and 1904 and Part II. deals with the years 1898, 1899, 1905, and 1906.

The question of school influence can be approached in many ways. In the first place, the day of the week on which the onset of each case occurs can be ascertained. By this method one can see on which day most cases arise, and further, whether Saturday and Sunday, days of non-attendance at school, produce any influence in lessening the number of cases on certain days following, allowance being made for incubation. Again comparison can be made between the holidays and the school terms in relation to the days of onset. It is of importance also to ascertain if, as regards the day of the week, the onset in infants and adults corresponds or not with the results obtained in school children.

A second method of approaching the subject consists in ascertaining the total number of cases occurring among children of school age during the holidays and comparing this with the number of cases occurring during an equal period of time before and after the holidays. Further, the effects of the holidays on infants and adults must be compared with that in *children of school age*. One might expect infants to show only a slightly diminished incidence during the holidays. In adults also a fall may be expected, proportionately greater, however, than in infants, owing to the diminished number of cases amongst school children during the holidays. This fact, of course, would tend to lessen the number of cases in infants also, but the greater amount of contact during the holidays between infants and those members of the family who are of school age will in all probability counterbalance the diminished prevalence of scarlet fever amongst the latter. In adults the amount of contact is not increased as they are at work all day and are exposed to infection from school children mainly in the evening whether the schools are open or not; this observation refers chiefly to male adults but it is applicable in a less degree perhaps to females also, many of whom are employed in mills, shops, &c.

In 1861 Trousseau, writing on scarlet fever and measles, stated that in neither could the latent period be rigorously determined in the present state of our knowledge. Obermeier, writing somewhat later, stated that the latent period was unknown. Murchison, in the Transactions of the Clinical Society, gives a series of 75 cases and states that in

0 could the latent period have exceeded 6 days.
73 the latent period could not have exceeded 5 days.
54 " " " 4 "
20 " " " 3 "
16 " " " 2 "
3 " " " 1 "

and further that the largest latent period made out in any of the cases was four and a half days, and that in only two of the cases was it as long as four days. His conclusions were that: (1) the duration of the incubation period may be only a few hours; (2) probably in a large proportion of cases it does not exceed 48 hours; (3) it very rarely exceeds seven days; and (4) these cases do not lend support to the opinion expressed by some that the latent period in scarlet fever is larger in adults than in children.

Other opinions as to the period of incubation given in literature are as under: Bains, two days; Withering, from three to four days; Gendron, not over four days; Bateman, from three to five days; and Gee, less than one week. Herschman quotes the following cases exhibiting a definite maximum limit of incubation:—

A girl... ... ... maximum onset within 24 hours.
A man ... ... " " 36 "
A child ... ... " " 2 days.
A girl (age 10) ... " " 2 "
A boy (" 4½) ... " " 1½ "
2 children ... ... " " 3 "

Gerhardt and Pons record two onsets, each within four days, in men, and Squire records ten cases with onsets as follows: in one case, 1 day; one case, under 2 days; six cases, 2 days; one case, under 3 days; and one case, under 4 days. Squire and Gerhardt agree that the usual period does not exceed seven days. Henoch quotes a boy, age nine years, with incubation period of 36 hours. Anderson cites a case (age six years) of the same duration, and Russegger out of four cases found the incubation period to be in one case (a child) within 12 hours; in two cases (children) within 2 days; and one case (a child) within 3 days. These cases quoted are instances of scarlet fever arising after a single contact with a known case of that disease. The most frequent range observed in the series given is from one to four days.

Now as a result of my analysis of the scarlet fever records for Manchester during the nine years under consideration Tuesday was found to be the day on which fewest cases commenced to be ill amongst those attending school (Table A) and Friday the day on which the greatest number of onsets occurred.

When the facts of each case of scarlet fever in infants and adults are inquired into we find that children of school age are the most frequent source of infection in infants and adults. One would expect, therefore, that at some period of time after Tuesday and Friday we should find the fewest and greatest number of cases respectively in infants and adults and this period of time represents the average duration of incubation. Reference to Tables D and E shows that Thursday is the day on which fewest infants and adults are seized with symptoms of scarlet fever and we have seen that Tuesday is the day on which fewest school children take it. Furthermore, Sunday and Monday are the days on which most onsets occur in infants, the corresponding days for school children being Friday and Saturday.

It appears reasonable to infer from these tables, in combination with a series of cases of known single "contacts" quoted above, that the most frequent period of incubation is two days, three days coming next. Though this period may hold true in the majority of cases one must allow for the occasional cases which occur on the first and fourth days, and it appears that a range of from one to four days as the latent period would cover the greater number of cases of scarlet fever. On the basis that such is the most usual range of incubation I have prepared the following plan, showing the days which may be expected to influence the number of onsets on any particular day of the week. The particular day influenced is shown above the black line; the second—or main day of influence—herein called the medium day, is shown between the thin lines.

Sun.	Mon.	Tues.	Wedn.	Thurs.	Fri.	Sat.
Wedn.	Thurs.	Fri.	Sat.	Sun.	Mon.	Tues.
Thurs.	Fri.	Sat.	Sun.	Mon.	Tues.	Wedn.
Fri.	Sat.	Sun.	Mon.	Tues.	Wedn.	Thurs.
Sat.	Sun.	Mon.	Tues.	Wedn.	Thurs.	Fri.

From this it will be seen that the infection in Sunday cases is mainly contracted on Friday and to a less extent on Thursday, while Wednesday and Saturday contribute fewer cases.

Monday cases are due mainly to infection on Saturday, a day on which the schools are closed, and to infection on Friday. As the medium day is Saturday one would expect fewer cases than on Sunday, for which Friday is the medium day. Monday also derives a proportion of its cases from infection on Sunday, again a day on which schools are closed.

Tuesday.—Here the medium day is Sunday and the day next in importance is Saturday—that is, the two main days concerned in the production of Tuesday's cases are days on which the schools are closed. One would expect, therefore, that Tuesday would appear at the bottom of the list.

Wednesday should show a slight increase on Tuesday's numbers, for, although both Saturday and Sunday play part in the production of its cases, yet Monday is the principal day and Sunday next in importance.

Thursday should show a distinct rise on Wednesday; the medium day here is Tuesday.

Friday.—Here all the contributory days are school days; the medium day is Wednesday.

Saturday.—Here, also, all the contributory days are school days.

One would expect therefore that Friday and Saturday should head the list, that Tuesday *should* be at the *bottom*, and Wednesday next. Monday should probably be next to Wednesday, as here the main day is Saturday, when the schools are closed, but Friday, the day next in importance in causing Monday's cases, is a day on which we have seen many cases should arise. Hence one would expect Monday to stand a little higher than Wednesday. Between Thursday and Sunday there should not be much difference. If anything, theoretically Sunday should have slightly more cases, as its main day is Friday, whereas Thursday's main day is Tuesday, when few cases should occur. This might be expected to cause a greater difference were it not that one of Sunday's contributory days is Saturday (when schools are closed). Consequently the greater risk of exposure on *Friday in Sunday's cases* (as compared with *Tuesday in Thursday's cases*) is partly balanced by the diminished risk on Saturday. The order on the above hypothesis therefore would be Tuesday, Wednesday, Monday, Thursday or Sunday, Friday or Saturday. It must be remembered that this theoretical order is made on the assumption that schools do exert an influence and it is made only for comparison with what one would expect and the actual facts as shown by the subjoined statistics relating to scarlet fever in the city of Manchester during the years 1898 to 1906 both inclusive.

To these statistics I must now direct attention. Table A shows the day of onset in all children aged from three to 13 throughout the year—i.e., both school days and holidays are included:—

TABLE A.

—	1898	1899	1900	1901	1902	1903	1904	1905	1906
Tuesday ...	52	106	211	189	178	163	182	175	222
Wednesday	57	120	214	214	174	160	158	189	147
Thursday ...	52	120	210	238	203	193	209	231	277
Friday ...	83	134	209	282	255	181	183	252	306
Saturday ...	78	123	241	231	210	190	198	247	290
Sunday ...	59	114	329	231	206	196	194	209	257
Monday ...	59	90	240	235	203	182	182	209	250

Order.	Total number.	Per cent.	Order.	Total number.	Per cent.
Tuesday ...	1478	12·55	Thursday ...	1733	14·71
Wednesday ...	1533	13·01	Saturday ...	1808	15·35
Monday... ...	1650	14·01	Friday... ...	1885	16·00
Sunday... ...	1695	14·39			

An examination of this table shows that Tuesday occupies the lowest position and Wednesday next lowest, followed by Monday with an increase of 117 cases on Wednesday's total. Next come Sunday and Thursday and at the top Saturday and Friday. The range between Tuesday and Friday, the lowest and highest respectively, is 3·45 per cent. It is difficult to explain why Saturday should always be below Friday—perhaps a desire on the part of school children not to lose a holiday leads to concealment in a few cases on that day. This table follows in a most striking manner the theoretical *order arrived at with the exception just noted.*

Table A1 relates to the same figures as Table A, only they are so arranged as to show a comparison between the two groups of years.

TABLE A 1.

	First group (1900–04).		Per cent.	Second group (1898, 1899, 1905–06).		Per cent.
Tuesday	923	or	12·86	555	or	12·04
Wednesday	920	,,	12·82	613	,,	13·31
Thursday	1053	,,	14·68	680	,,	14·78
Friday	1110	,,	15·48	755	,,	16·72
Saturday	1070	,,	14·92	738	,,	16·04
Sunday	1056	,,	14·72	639	,,	13·88
Monday	1042	,,	14·52	603	,,	13·20

This table shows the two groups of years compared, and though the order in each group is not identical, yet in the main they agree—in that in each Tuesday, Wednesday, and Monday are bottom and Saturday and Friday stand highest.

Table A 2 shows the day of onset in school children for that period *only* during which the schools were open (i.e., it excludes any cases arising during the holidays).

TABLE A 2.

Tuesday	1326	Saturday	1655
Wednesday	1395	Sunday	1550
Thursday	1696	Monday	1513
Friday	1741		

These figures give the days the following relative positions:—

	Per cent.		Per cent.
Tuesday	12·31	Thursday...	14·81
Wednesday	12·95	Saturday...	15·36
Monday	14·04	Friday	16·16
Sunday	14·38		

This table which shows the day of onset in school children and is strictly confined to children actually attending school (onsets during the holidays being excluded) very remarkably supports the theoretical order I have suggested except that in actual figures Thursday stands higher in the list than Sunday. I have, however, already mentioned that the difference one way or the other between these days might be expected to be only slight. With a view to see if this order held good in the holidays also I have prepared the following Table C, and a comparison between it and the preceding one is very interesting.

Table C shows the onsets in days of the week during the *summer and winter holidays for the whole nine years*:—

TABLE C.

	Total number.		Per cent.		Total number.		Per cent.
Tuesday	152	or	15·11	Saturday	153	or	15·21
Wednesday ...	138	,,	13·72	Sunday	145	,,	14·
Thursday	137	,,	13·62	Monday	137	,,	13
Friday	144	,,	14·31				

In Table C it will be observed that during the holida the position of Tuesday and Wednesday relative to the oth days of the week no longer follows that seen during th period when the schools are open. The tendency for an big difference between the days is much less, the onse appearing to be distributed much more evenly over all th days of the week. In the case of children attending scho the range between the highest and the lowest day is 3·8 whereas during the holidays the corresponding range 1·59. The above figures relate exclusively to children c school age.

I will now briefly refer to the corresponding figure relating to infants and adults. Table D shows the day c onset in infants (0–3 years).

TABLE D.

	Total number.		Per cent.		Total number.		Pe cent
Tuesday	607	or	13·96	Saturday	610	or	14·0
Wednesday ...	610	,,	14·03	Sunday	686	,,	15·7
Thursday	580	,,	13·35	Monday	639	,,	14·7
Friday...	614	,,	14·17				

A consideration of these figures relating to infants show that the relative positions of the days vary greatly from tha seen in school children. In the case of the former Tuesday and Wednesday are no longer in the lowest position and further, Sunday and Monday displace Friday and Saturday at the opposite end of the list. The inference that may be drawn from these figures has already been referred to.

Table E shows the day of *onset in* adults (13 years and onwards).

TABLE E.

	Total number.		Per cent.		Total number.		Per cent.
Tuesday	311	or	14·73	Saturday	334	or	15·82
Wednesday ...	278	,,	13·17	Sunday	316	,,	14·97
Thursday	274	,,	12·98	Monday	313	,,	14·82
Friday	285	,,	13·51				

Here again it may be noted that Thursday occupies the lowest position and that Saturday, Sunday, and Monday stand high.

We may next direct our attention to another point of view from which we may study school influence. If schools do materially assist in spreading scarlet fever one would expect that during the holidays the number of cases among children of school age would be considerably less than during a corresponding period both before and after the holidays and further the fall in the number of cases during the holidays should be a gradual one, reaching a *minimum* at the end of the holidays. In addition, one would expect a rise in the incidence shortly after the reopening of the schools corresponding roughly with the period of incubation. I have prepared tables and charts which record the effects as seen in the Manchester schools. Sir Shirley Murphy in his report to the London County Council, 1894, discusses this subject and shows that in 1892 and 1893 a marked decrease occurred in the number of cases notified at a time which corresponded with the summer holiday of the children attending London School Board schools, and that there was a marked increase in the number of cases notified at a time which corresponded with the reopening of these schools, due allowance being made for the period of incubation and delay in notification. He also showed *that* this decrease was especially marked in the case of children of school age. I extract the following figures and remarks from his report :—

	0–3 years.	3–13 years.	13 years onwards.
4 weeks preceding	204	1026	220
4 ,, *of holidays* ...	189	808	181
4 ,, following... ...	176	1079	175

or, represented in percentages—

	0–3 years.	3–13 years.	13 years onwards.
4 weeks preceding... ...	0	0	0
4 ,, of holiday ...	−7·4	− 21·2	−17·7
4 ,, after	−6·9	+ 33·5	−3·3

"It will be seen that at each age there was a decrease in the number of cases *in the second period, but that this decrease was most manifest* in children at the school age. Again, while there was a decrease in the third period amongst infants under three and amongst persons over 13 the number of cases among children of school age increased by 33·5 per cent. These figures accord with a hypothesis that the interruption of the school operation was responsible for some part of the decrease in the second period of cases among children at school age, and that the increase among these children in the *third* period was largely due to the reopening of the schools."

Through the courtesy of Mr. C. H. Wyatt, director of education in Manchester, I have been supplied with the dates of the holidays during the nine years covered by this inquiry and have thus been able to arrive at figures showing the relative number of cases before, during, and after the holidays, all three observations being for a similar period of time.

Table F shows the number of cases for each year during the three periods in question :—

TABLE F.

Summer Holidays (Ages 3–13 Years).

	1898	1899	1900	1901	1902	1903	1904	1905	1906
Before ...	21	53	116	135	79	86	122	88	143

After	514	+19·5	1134	+23·4

Table F 2 shows the corresponding figures for infants (0–3 years).

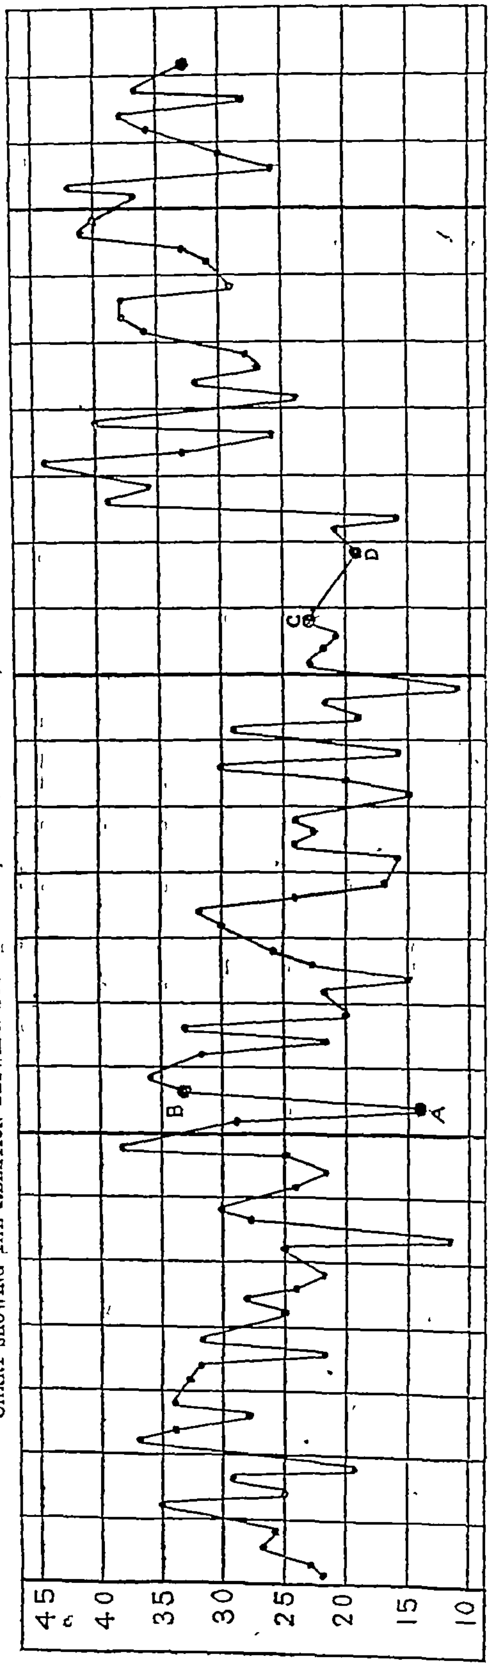

CHART SHOWING THE RELATION BETWEEN SCHOOL TERMS, SCHOOL HOLIDAYS, AND THE INCIDENCE OF SCARLET FEVER.

A, Last day of term. B, First day of holidays. C, Last day of holidays. D, First day of term.

TABLE F 2.

		Per cent.
Before	514	0
During	471	–8·4
After	51	+0·8

From these statistics relating to the Manchester schools it will be seen that both in infants and adults there is a decrease in the number of cases during the holidays, amounting in infants to 8·4 per cent. and in school children to 17·4 per cent. Again, in the period of the reopening of the schools, while there is an increase among infants there is a very much greater increase in the proportion of school children affected, such increase amounting to 25·5 per cent. These figures confirm those published by Sir Shirley Murphy in 1894.

In order to ascertain the manner of the decrease and increase I have prepared a chart which summarises seven of the years. (Two are not included as the holidays in those years (1898 and 1899) were shorter than during the seven succeeding years, in all of which the holidays were of equal length.) Reference to this chart will show that there is a gradual fall—subject to occasional exacerbations throughout the holidays—this fall reaching a minimum on or about the end of the holidays, and further that within four days after the schools reopen there is a very sudden increase in the number of cases of scarlet fever, such increase being more or less sustained throughout the month following the reopening. From charts prepared for each year it was evident that the fall during the holidays seen in the chart produced was not due to any great fall in a particular year but represented the summation of gradual falls in each year. The chart also shows extremely well the sudden increase in cases on the fourth day after reopening. It must be remembered that in all cases throughout this report onsets, and not notifications, are referred to, thus obviating any error due to delay in notification.

Conclusion.—In view of the facts shown in the foregoing tables and chart I think there can be little doubt that schools do assist in the spread of scarlet fever. The influence exerted may not be very great, but it exists and is by no means entirely negligible. On the very probable hypothesis that the most usual latent periods are two or three days (more especially two) and that with few exceptions the range is one to four days, I showed that the theoretical order in which the days of the week should stand, if schools do exert an influence, is as follows: Tuesday should be lowest, followed by Wednesday and Monday; Thursday and Sunday should not be widely separated, and Friday and Saturday should stand at the head of the list.

We have seen that Saturday is the day of the week on which we should expect the greatest number of cases of scarlet fever and after Saturday—Friday. Friday, however, is the day on which most cases actually occur. I have ascribed this slight reversal of the expected relation to the probable concealment of slighter attacks on Saturday, which is a holiday. Reference to Tables A and A 2 shows that such is the case in the particular period of time under consideration (1898 to 1906 inclusive) and for each of two parts of this period. The actual facts strongly support the assumption that two days is the medium latent period, closely followed by three days. Further, we have seen that in the holiday period this order is no longer maintained, but that the onsets are much more evenly distributed over all the days of the week (C).

The tables relating to onsets in infants and adults further support the inference drawn from Tables A and A 2—viz., that the closure of the schools on Saturday and Sunday is responsible for the fewer onsets on Tuesdays and Wednesdays. If such order had obtained in infants and adults some other explanation would have to be sought (Tables D and E). Viewed from the other aspect this influence is also seen to exist. In London a very considerable diminution in the prevalence of scarlet fever was experienced during the holiday period in all ages, but this diminution was most marked among children of school age. The figures for Manchester bear out in a striking manner the experience of London, and, further, the chart shows that this decrease in prevalence is a gradual one, reaching a minimum near the end of the holidays, and that within a few days (four) of the schools reopening there is a very marked increase of prevalence—an increase which is then sustained. Comparison with the London figures in this respect cannot be made, as the latter figures refer to notifications and the individual days are not differentiated.

Table F shows that the diminution in prevalence during the holidays obtains in both groups of years. It will be noticed that in two out of the nine years (1902 and 1905) there is an increase instead of a decrease during the holidays. This may have been due to accidental circumstances—e.g., a small epidemic in one particular neighbourhood, or to the force of an ascending epidemic. We cannot fail to be struck with the sudden rise in the number of cases when the schools reopen after the summer and Christmas holidays. It is not in this manner that scarlet fever usually ascends and we are led to inquire whether, perhaps, similar concealments are not practised during the holidays especially towards their termination, concealments resulting in an extension of the disease beyond the normal? It is not suggested that the depression of scarlet fever among school children during the holidays is other than real, but it may be that it is not so great as it appears to be from the facts obtainable. Those engaged in public health work are fully cognisant of the frequency with which overlooked and wilfully suppressed cases of scarlet fever are sent to school by ignorant parents. Many of such cases are detected by the occurrence of subsequent cases in the same house or school causing a strict inquiry to be instituted. One cannot believe, however, that all such overlooked and suppressed cases are detected and they in consequence continue to spread the disease.

We know that other diseases—e.g., ophthalmia, ringworm, and scabies—are frequently contracted at school. It is, of course, essential that the work of educating the children of the nation should continue, but it is no less essential that they should be protected as far as possible. This would appear to lie in the direction of a furthering of the present policy of educating the school teachers to recognise the early symptoms and signs of the principal infectious and contagious diseases, and in the establishment of a thorough and systematic medical inspection of all school children. The manner, however, in which this is to be performed does not lie within the province of this report.

Manchester.

RESCUE WORK IN MINES: LESSONS FROM THE COURRIÈRES MINE CATASTROPHE IN FRANCE.

BY THOMAS OLIVER, M.A. DURH., LL.D. GLASG.,
M.D. GLASG., F.R.C.P. LOND.,
PROFESSOR OF PHYSIOLOGY AT THE COLLEGE OF MEDICINE AND
PHYSICIAN TO THE ROYAL VICTORIA INFIRMARY,
NEWCASTLE-UPON-TYNE.

WHILE experience and statistics show that the occupation of the coal miner is not *per se* an unhealthy one, the risks attendant upon his calling are such as to render coal-getting one of the most dangerous occupations man can follow. The appalling catastrophe at Courrières in France, whereby on March 10th, 1906, 1100 men and boys lost their lives, stirred up an amount of public sympathy and consideration for a class of men who at certain times and under certain conditions go to work with less certainty of return than men engaged in most occupations. This uncertainty is well brought out in the few lines written by our local poet, himself a miner, Joseph Skipsey, in verses that are well known in the North of England and which confirm the impression I have tried to convey:—

> "Get up," the caller calls, "get up,"
> And in the dead of night,
> To win the bairns their bite and sup,
> I rise a weary wight.
>
> My flannel dudden donn'd, thrice o'er
> My birds are kissed, and then
> I with a whistle shut the door
> I may never ope again.

When all nations were, as one, united in expressing to France their deep regret at the great loss of human life at Courrières, Germany in her desire to give practical proof of her sympathy and of her eagerness to test the value of rescue apparatus offered at once to send trained men to assist in recovering the imprisoned miners, an invitation which was as gratefully accepted as it was cordially conveyed. This humane and prompt act on the part of a great nation is an illustration of the fact with which we as medical men are familiar, that in the application of science to the saving of human life there is no such thing as nationality. The disaster at Courrières has been made the occasion of reviving the subject of rescue work in mines and of again enforcing upon mineowners and medical men engaged in colliery practice the necessity of coming to some conclusion as to the best methods to be adopted in trying to reach and to remove miners imprisoned in a pit after an explosion. That there is some urgency in this matter is shown by the fact that since the Courrières catastrophe in France there has occurred in Great Britain mining disasters which, if on a small scale, have yet been attended by loss of life, as witness the colliery explosion at Wingate, county Durham, in October of last year, when 24 miners lost their lives. Subjoined is a summary of the explosions of fire-damp and coal-dust in the several mines inspection districts of this country, kindly forwarded to me by Mr. Walton Brown of the Mining Institute, Newcastle-upon-Tyne.

Year.	Fatal accidents.			Non-fatal accidents.	
	No.	Deaths.	Injured.	No.	Injured.
1900	25	45	29	128	178
1901	21	125	47	120	167
1902	23	63	33	133	172
1903	11	14	10	134	183
1904	17	22	25	134	190
1905	14	178	46	124	173

The figures for 1906 are not yet available.

The column "fatal accidents" is so named owing to the fact that in each particular accident a death or deaths occurred. The above table gives information as to the large number of lives lost every year in British collieries from explosions, notwithstanding the excellent ventilation of the mines and the vigilance exercised over the workmen.

It is unnecessary to draw attention to the sad spectacle exhibited, to the terrible havoc to human life, and the wreckage of plant observed in a coal mine after an explosion, nor need we discuss the question of the causes of explosions other than make this statement, that in addition to explosions the result of fire-damp the ignition of coal-dust in a dry mine by a naked light is now regarded as one of the most frequent causes of colliery explosions. Nor need we discuss at any length the dangerous gases met with in coal mines beyond making mention of the extremely poisonous character of the carbon monoxide that follows an explosion and the less poisonous nature of carbonic acid. In coal pits miners can go on working in places where the percentage of carbonic acid is so high that a candle will not burn, but there are limits to which this should be attempted. On the other hand, exposure to very small percentages of carbon monoxide even for a short period may give rise to serious symptoms.

While after a colliery explosion many of the miners must have been killed by the shock and by the flame, as indicated by the marks of burning, and its destructive effects, as exhibited by the corpses, by far the larger number have fallen victims to carbon monoxide poisoning. When an explosion occurs there is first a deflagration or a sudden combustion attended with flame and gas. There is an enormous gaseous expansion, owing to the heat produced, and this is followed by contraction. The hot gases pass along the way of least resistance and having exhausted the air there is created a void behind them. An explosion of fire-damp and oxygen is followed by a contraction, so that when the watery vapour is condensed the volume of the gas is found to have diminished two-thirds. The question has been suggested as to whether under these circumstances effects may not be produced upon the miners akin to those observed in caisson disease as the result of sudden compression and decompression. The explosion determines for a brief period a very elevated temperature and this is followed by a sudden fall. Dr. Firmin Dervieux, in discussing the medico-legal aspects of the Courrières catastrophe,[1] says that on the bodies of miners killed in explosions the effects of two different causes may be found—viz., wounds produced from without inwards and consequent upon the enormous pressure of gas at the moment of the conflagration, also wounds produced from within outwards during the cooling and contraction of the gases. These latter wounds are present only upon the bodies of dead miners found a little distance from the site of the explosion or in a gallery ending in a cul-de-sac. In this way may be explained the ecchymoses and multiple injuries when the wounds have been caused from without inwards and the tearing and rupture of the tissues and organs when developed from within outwards. In the blood of coalminers killed in this manner no trace of carbon monoxide hæmoglobin is found on spectroscopic examination. Many of these men are killed by the column of gas suddenly striking them with all the force of a projectile. It is this shock which kills. It may be so powerful as to tear asunder the limbs from the body and hurl them several yards away from the spot. Apart from the severity of the wounds the proof that the miners under these circumstances are killed suddenly is the absence of carbon monoxide hæmoglobin in their blood. On many of the dead bodies found at Courrières there were marks of burning. It is sometimes necessary to find out whether the burns occurred before or after death. The miners who perished in the explosion by expansion of the flame were not burned in the ordinary acceptation of the term. The burns inflicted under these circumstances are not serious, but as the air in the mine contains a large quantity of fine coal dust which becomes incrusted upon the skin of the injured men the black appearance of the body at first suggests a burn of the third degree. Nearly all the burns on the body are the result of the hot air. In the Courrières disaster there was, according to Dervieux, no flame in the ordinary sense of the word, or if so it must have been for only a very short period, for the clothes of the miners were not burnt, although the skin underneath was singed. It was not always easy at Courrières to distinguish between the miners who had died from burns and the corpses of the men who had been exposed to the action of hot gases. A spectroscopic examination of the blood did not always solve the problem. There were the charred bodies of men who had been burnt by the hot gases or who had died as the result of carbon monoxide poisoning before the fire reached them. Is it possible for absorption of carbon monoxide by the blood to occur in a dead body? I have exposed the dead bodies of animals (rats and mice) to fairly strong percentages of carbon monoxide gas for 24 hours and for as long as a week without finding any trace of carbon monoxide in the blood. The probability, therefore, is that no absorption takes place. In the Courrières mine the largest number of deaths was due to carbon monoxide poisoning. Several of the bodies were found in the position in which the miners had been working when death suddenly overtook them. The explosion had propelled a column of gas containing carbon monoxide, and as the gas became cooled in passing along the galleries the carbon monoxide suddenly poisoned the workmen who had inhaled it. When the percentage of this gas is enormous, as it must be after an explosion in a coal mine, and poisoning occurs on a large scale convulsions are absent. It is in the slowly induced forms of carbon monoxide poisoning that the locomotive powers of men who have been exposed to it become enfeebled. Of these slower forms of poisoning there were also evidences in Courrières, for owing to the small percentage of the gas in some places the men detecting the "bad air" and experiencing headache and vertigo had tried to save themselves, but as the gas travelled quicker than they could it continued to exert its evil effects. Some of the miners thus overpowered had fallen on their knees, others overcome by coma had fallen prostrate.

One of the most painful and distressing circumstances to the relatives of the deceased miners was the difficulty they had of recognising the bodies of their friends owing to the injuries and the extent to which putrefaction had advanced. To the rescue men the rapidity with which the corpses of the miners and horses putrefied and the repulsive odour that prevailed caused the work not only to be extremely unpleasant but a menace to their own health. While after an explosion it is the living and not the dead that have to be sought for, the continued presence of decomposing bodies in a mine becomes a risk to life. It appears that several of the wounded miners who were brought to the surface only lived a few days. Nearly all of them died from pneumonia either due to their having respired the hot air in the mine or as a complication of carbon monoxide poisoning. Dr. Lourties states that several of the miners died from pneumonia from 50 to 60 hours after the explosion. The inflammation of the lungs developed in each instance with great rapidity and was accompanied by high temperatures. The lesions in the lungs were extensive; they were lobar and not lobular and there was a greater tendency for the right than the left lung to be affected The proof that some of these miners who subsequently succumbed to pneumonia had respired carbon monoxide is to be found in the symptoms they complained of. The men said they had headache, vertigo, and an overpowering inclination to sleep, while in other patients the limbs were paralysed. In some of my own experiments with carbon monoxide gas I have found animals die from pneumonia and small hæmorrhages into the lungs two and three days after exposure to the gas. Pneumonia is occasionally, therefore, a sequel to the inhalation of carbon monoxide gas.

---

[1] Annales d'Hygiène Publique et de Médecine Légale, December, 1906.

As far back as 1846 Sir H. T. de la Beche and Dr. Lyon Playfair reported that after a colliery explosion there is a sufficient quantity of oxygen present in the air of the pit to support the respiration of the surviving miners provided there is no excess of any poisonous gas present as well. Three years subsequently Dr. John Hutchinson proposed that after an explosion men should carry into the mine bags containing four or five cubic feet of air, so that they could exist in the mine for at least half an hour, the expired air escaping into the atmosphere. Hutchinson was afraid to recommend pure oxygen. In 1880 Henry Fleuss invented his apparatus which was used with some success in the following year at Seaham colliery. Two years after this David Rhys Jones invented his apparatus whereby oxygen could be carried by men into a mine after an explosion and made capable of sustaining respiration for half an hour. Since then considerable improvements have been made in rescue apparatus to which attention will be invited further on. To show how entombed miners after a colliery explosion may be reached and rescued and to enable firemen to enter premises filled with smoke and irrespirable gases is work upon which the physiologist, the chemist, and the mining engineer can unitedly bring to bear their respective sciences. In the earliest attempts men were provided with a tube, one end of which they placed in their mouth or attached to a helmet such as that worn by divers, and through this tube fresh air was pumped from without, but the disadvantages of such simple methods are that the tube might become kinked and owing to the distance the men might have to travel that the tube would become extremely heavy. It is therefore necessary to have an autonomous respiratory apparatus which will enable a man to carry with him a sufficient quantity of air to render him independent of the air outside and which shall be so secure as to cut him off from the possibility of breathing poisonous gases. When [illegible] air was tried in the earlier experiments it [illegible]s found that men could support themselves in a poisonous [illegible] for 20 minutes. Since then many improvements have been effected in rescue apparatus. Abroad one of the pioneers of the movement is Dr. Guglielminetti, whose experience as an aeronaut and an Alpine climber has given him many opportunities of testing the value of compressed oxygen and whose invention is the rescue apparatus now adopted by the Draegerswerk at Lubeck. The ordinary atmospheric air which we breathe contains in volumes 79·04 per cent. of nitrogen, 20·93 of oxygen, with about 0·03 of carbon dioxide, while expired air contains 79·6 volumes of nitrogen, 16 04 of oxygen, and 4 volumes of carbon dioxide. About the same qantity of carbon dioxide is given off in expiration by man as there is of oxygen absorbed. There is a kind of mutual interchange between these two gases. The nitrogen, on the other hand, plays no part in the respiratory interchanges. It is quite inert, and while opinions are divided upon the following procedure this circumstance is one of the reasons advanced for not using ordinary air in rescue apparatus, since to carry a sufficient amount of compressed atmospheric air there is too much weight added by the nitrogen, which after all is a gas not required for breathing purposes. By dropping the nitrogen the apparatus can be reduced to one half of the original weight. In the "aerolith," which is supplied by Simonis and Co, Norfolk-street, London, and which is identical with that invented by M. Suess, a mining engineer of Witkowitz, liquid air is used. I have seen the "aerolith" worn and was impressed by its utility. The drawback to it is the rapidity with which the nitrogen boils off compared with the oxygen. One of the strongest testimonies in its favour appears in a lecture recently delivered before the Paris section of the Société de l'Industrie Minérale by M. Weiss, who had carried out a series of experiments in Austria under the instruction of the Minister of Public Works, and who speaks of the apparatus when slightly modified as being extremely practical and capable of rendering service where workmen have to traverse galleries exposed to poisonous gases.

Similar experiments have been carried out in Germany with apparatus of the portable class and which provide for the delivery of oxygen to the wearer and absorption of the carbonic acid. Under this type of appliance come the Draeger, Meyer, and Shamrock. In Germany the "pneumatogen" has not been subjected to actual trial after an explosion, but it has been experimentally tried at the school of mines at Bochum in Westphalia. There the students attending classes are regularly drilled in the use of rescue apparatus. Opinions are divided as to whether the gas supplied to the wearers should be pure oxygen or liquid air. Some mine managers favour the liquid air apparatus on the ground that it is more secure, while others are sceptical as to the practical utility of all forms of rescue apparatus. Notwithstanding this the mines regulations of Breslau (Silesia), January, 1900, require that "in coal mines there shall be provided at each shaft two portable sets and a greater number if the engineer of mines shall so direct. The mine owner is expected to see that these appliances are always in working order, and that the workers, to a sufficient number, are exercised in their use. In Westphalia no official regulations are in force.[1] Certain mining companies have organised brigades and are thus able to render assistance should such be required. It is not deemed expedient to keep the apparatus at the bottom of the pit but in a special chamber on the surface which is in telephonic communication with the bottom. At the Rhein Elbe mine at Gelsenkirchen 25 men have been trained in the use of the respiratory apparatus and in the extinction of fires. The men are selected on account of their good physique and sobriety and are well disciplined. Once they have become accustomed to the apparatus they are drilled every three months. The exercises the rescue men go through are somewhat onerous. Many of the men complain of pains in the head but at the Altofts experiments, to which I shall allude presently, there was no complaint of headache; the men whom I saw seemed quite fresh on coming out of the galleries.

In an ordinary way a man requires about 500,000 cubic inches of air per 24 hours. Half a cubic foot or 864 cubic inches of carbonic acid are given off per hour and the same quantity of oxygen is absorbed. A miner should therefore be supplied with not less than one cubic foot of oxygen per hour. In making up a respiratory apparatus to be worn by men in a mine care should be taken, if oxygen is to be the gas supplied, that it is pure and free from nitrogen. Only 4 per cent. of the oxygen taken into the lungs at a particular time can be taken up by the blood; the remainder is exhaled without being utilised; but with this loss of 4 per cent. of oxygen there appears 4 per cent. of carbon dioxide in the expired air. During muscular work the amount of carbonic acid is increased. As this gas tends to accumulate it becomes a source of danger; consequently arrangements have to be made in all forms of apparatus for its removal by passing the expired air through tubes containing caustic potass. Air containing 1 per cent. of CO_2 causes headache, but it is not until 10 per cent. is reached that unconsciousness, according to Haldane, is produced. In all forms of rescue apparatus the oxygen should escape automatically from the cylinder and be carried directly by a tube into the mouth of the wearer or into the interior of his helmet. As the air that has been breathed becomes hotter and the increased temperature itself becomes a source of inconvenience and uneasiness the exhaled air as it circulates in the apparatus passes through a refrigerator. That absorption of the carbonic acid is complete in the apparatus has been demonstrated by the analysis of the contained air by Gréhaut who failed to find any trace of the gas in the apparatus that was used by the German rescue party at Courrières

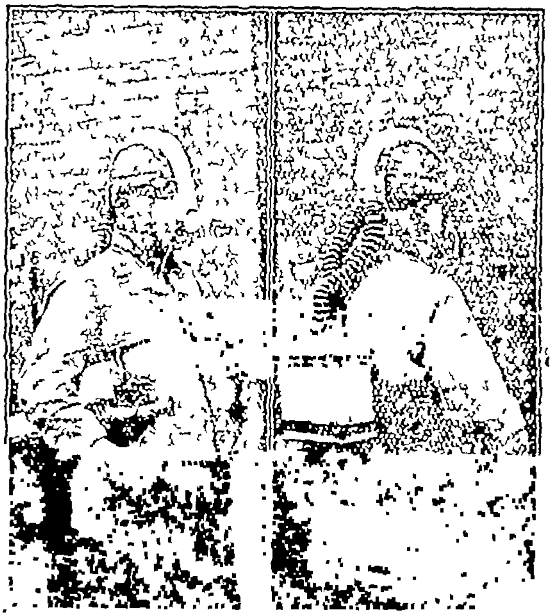
Hitherto I have said little of what our own country has been doing in this matter. A few years ago it was proposed by the Midland Institute of Mining, Civil, and Mechanical Engineers to establish rescue stations at which men might be trained in the use of live-saving apparatus in colliery explosions. In 1899 Mr. W. E. Garforth of Altofts Colliery, Normanton, constructed an artificial gallery in which experiments with various forms of respiratory apparatus might be tried. Through the kindness and courtesy of Mr. Garforth

---

[1] The Colliery Guardian, March 29th, 1907, p 579.

I have been the witness of some of these experiments. The gallery is 150 feet in length and six and a half to seven feet high. It is air-tight and is divided so as to form three parts of a square. It is provided with windows, through which when the atmosphere inside the gallery allows of it the experiments can be watched. The interior is so arranged as to resemble as far as possible portions of a coal mine after a violent explosion. Here and there portions of the roof are supposed to have fallen, the floor is uneven and covered with débris, large pieces of timber have been broken and blown out of their places, and in consequence of the many falls of stone the space between the floor and the roof is so contracted that a man can just crawl through. Into this gallery noxious fumes and smoke from burning sulphur, timber, leather, &c., are pumped and in a few minutes it is impossible to breathe owing to the stifling character of the atmosphere and the pungent and irritating nature of the smoke. Four men, each provided with an electric lamp and wearing Mr. Garforth's respiratory apparatus, all of whom had undergone a training, entered the gallery filled with noxious fumes.

The men work in couples and in the gallery they have to encounter all the physical difficulties likely to be met with in a coalmine after an explosion, including the presence of poisonous gases. They have also to extinguish a fire and bring out of the gallery a dummy dressed as an injured or dead miner and weighing 160 pounds. To accomplish this the rescue party, with the respiratory apparatus fixed on their backs and wearing helmets, have not only themselves to crawl upon their stomach up steep inclines, which in some places rise 4 feet from the floor, strewn with rough stones and pieces of coal, but to pull and push the ambulance with the dummy in it. They have also to crawl and push it through an iron pipe 18 inches in diameter. The men are in the gallery for two and a half hours on an average and during that time they not only walk and crawl a distance of two and threequarter miles but undergo, as indicated, all kinds of severe muscular exertion. In Mr. Garforth's first experiments the men wore a pneumatophore and a Meyer helmet, and the results obtained are published in the Transactions of the Institution of Mining Engineers, Vol. XXII., 1901–02. On that occasion Mr. T. Marshall Nicholson and Dr. Alister Mackenzie of Leeds took records of the pulse-rate and of the temperature of the men before entering the gallery and on leaving it. After a few minutes' exposure their pulse-rate frequently rose from 74 to 150 and the temperature from 97° to 99 2° F., but this may have been partly the result of nervousness. On leaving the gallery the men complained of headache which within half an hour usually disappeared, also of giddiness and nausea which were also transitory. Since that date Mr. Garforth, with the experience gained whilst recovering bodies after colliery explosions at Dukinfield and Altofts, has improved his apparatus, which is known as the "Weg" and which weighs 21 pounds 5 ounces. The "Weg" apparatus consists of two steel cylinders connected with each other and containing compressed oxygen. From these cylinders the oxygen passes through a stop valve to a branch pipe on which a pressure gauge is fixed, so that the wearer of the apparatus can see what pressure of gas he is using and can thus be warned of the necessity of returning to the shaft or a place of safety in the mine on signs of the gas becoming exhausted The supply of oxygen to the wearer is regulated by a "lung governing valve," the theory being that as the inhalation of air by the action of the lungs is intermittent the supply of oxygen should also be the same. It is unnecessary to describe the apparatus fully. The oxygen is conveyed to the mouth of the wearer and thence to the lungs, provision being made for carrying away the expired air from the mouthpiece through a valve downwards, so that there is no chance of the impure or exhaled air returning to the lungs during the next inhalation The expired air subsequently passes through potassium hydrate and loses its carbonic acid, while the nitrogen passes on. Arrangements also exist for cooling the expired air Equipped with the "Weg" apparatus one miner remained in the gallery for three hours and ten minutes, and during that time walked and crawled two and three-quarter miles. In another experiment five explorers wearing the apparatus were in the gallery one hour and ten minutes, during which time, in addition to walking and crawling, they cleared away several stones from 50 to 80 pounds weight each, representing falls of roof, carried the ambulance stretcher over falls, passed through a sheet-iron pipe two feet in diameter, discovered a dummy workman weighing 140 pounds, dragged the dummy in the stretcher, the two together weighing 200 pounds, over falls to the mouth of the gallery, returned again, passing over falls, to the far end of the gallery, a distance of 90 feet, with fire extinguishers and put out a fire. Although one or two of the men appeared to be hot on coming out of the gallery they were otherwise quite fresh.



A front and back view of Mr Garforth's original "Weg" apparatus

Mr. Garforth in this country, Dr. Guglielminetti and others on the continent, including the makers of the Draeger and other types of apparatus, have shown that forms of apparatus have now been invented the utility of which cannot be denied. The experiments at Altofts colliery which I have had the opportunity of seeing have indicated to me that men provided with the apparatus can pass into poisonous and irrespirable atmospheres, remain therein for from two to three hours, and undergo extremely hard exertion without experiencing any bad effects. The apparatus is as invaluable to firemen as it is to coal-miners. There should be no fire brigade in large towns without some such apparatus and the members should have opportunities of being trained in their use. Some of the forms of apparatus that are now in the market are neither cumbersome nor heavy, for as stated I have seen men wearing the apparatus crawl through an 18 inch iron pipe at the Altofts colliery experiments By many mine managers rescue apparatus of all kinds is looked upon with disfavour, and consequently there is little disposition to give them a trial. To the necessity of the helmet portion of the apparatus there are brought forward many objections, one of which is the death of a miner at Courrières, but as the miner in question was known to have been ignorant of the working of the apparatus, had gone into the pit unobserved and without permission, and had not adjusted the helmet properly, his death was not due to a defect in the apparatus, for it was subsequently tested and found to be in perfect order. Come what may the rescue of entombed miners in a pit after a colliery explosion will have to be dealt with, and apparently on such lines as those discussed in this paper. Physiology and mining engineering will have to tackle the problem and there is not the least doubt that it will be solved. Meanwhile the call is for continued experiment and experience and for the establishment of rescue brigades in mining centres where men can be trained. How this training should be carried on and where, also the kind of apparatus that should be adopted, are questions that need not be dealt with in this paper, which will have served its purpose if it arouses interest in the important subject of rescue work in mines.

Note.—Through the kindness of Major Cordier I recently had the opportunity of seeing at the barracks of the Sapeurs-Pompiers, Paris, the rescue appliances worn by the firemen of that city. While these are much of the same design as those described above the apparatus invented by one of the officers, Lieutenant Vanginot, is of special interest. Compressed air is used. When the pressure in the cylinder falls below a certain point a shrill whistle is heard. This is meant to be a warning to the wearer that the supply of air is drawing to a close.

Newcastle-on-Tyne.

TWO CASES OF CEREBRAL ABSCESS.

BY J. MICHELL CLARKE, M.A., M.D. CANTAB., F.R.C.P. LOND.,

PROFESSOR OF MEDICINE AT UNIVERSITY COLLEGE, BRISTOL; PHYSICIAN TO THE BRISTOL GENERAL HOSPITAL.

THE following two cases of cerebral abscess present special features of interest.

CASE 1.—The patient, a girl, aged 16 years, had always enjoyed good health and there was no history of any ear disease; for the past three years she had worked very hard and had suffered frequently from colds in the head. On Dec. 22nd, 1904, she went to bed in apparently good health but on the following morning she could not get out of bed, and on that and the next day when she attempted to stand she fell down. On the 25th she was seen by Dr. A. B. McKee, who found some rigidity with loss of power in the right arm and leg, and on the evening of that day she had an epileptiform convulsion with clonic spasms of the right arm and leg. On the 26th the right arm was almost completely paralysed and the leg could only be moved with much difficulty; there were no facial paralysis, no aphasia, and no loss of consciousness. The pupils were dilated. On the 29th and 30th drowsiness came on and gradually deepened, and the respirations became shallow. Late on the 31st she was admitted into the Bristol General Hospital and when seen on Jan. 1st was in the following condition. She lay on her back in a semi-comatose state, only responding when spoken to loudly. She opened the left eye a little way, the right not at all. The eyes deviated slightly to the left. The left pupil was larger than the right, both being moderately dilated, and responding feebly to light; this response was slower on the left side. The right side of the face in all parts and the right arm and leg were paralysed and flaccid. Sensation so far as could be tested by a pin-prick was everywhere unaffected. The superficial reflexes were absent on the right side but present on the left; the deep reflexes were all exaggerated on the right side. There was no optic neuritis, but the edge of the left optic disc was hazy and the veins were full. There was constipation and incontinence of urine, which contained a trace of albumin, no sugar, and no casts. The pulse was 76 and regular, the respirations were 20, and occasionally of the Cheyne-Stokes type, and the temperature was 98° F. in the right axilla and 97° in the left. The tongue was thickly furred. The thoracic and abdominal organs were healthy. The ears were normal and no nasal disease was discovered. She was able to swallow liquid but not easily. A spinal puncture was made and a little cerebro-spinal fluid was obtained, which was normal in character and proved sterile. On the 2nd the condition was unaltered, except that the drowsiness was greater, and on the 3rd this had passed into profound coma. The abdomen became retracted with a marked tache cérébrale. There was no recurrence of the convulsion of Dec. 25th. The temperature remained at from 97° to 98° until the 3rd, when it rose to 100° and stayed at that point until death occurred. The pulse was 84 on the 2nd, 96 on the 3rd, the patient dying on the morning of the 4th from failure of respiration. At the post-mortem examination the only evidence of disease was in the brain; this weighed 2 pounds 10 ounces. On removing the dura mater both hemispheres were found to be bulged and their convolutions to be flattened, the left being especially so, and just behind the upper end of the fissure of Rolando, close to the longitudinal sinus, was an area of local bulging, soft and fluctuating, over which the pia-arachnoid was thickened, with some soft adhesions to the dura mater. This swelling led into an abscess cavity of the size of a Tangerine orange, which was full of grumous, greenish pus and broken-down cerebral tissue. The abscess had a well-defined, firm, membranous wall. It was situated in the centrum ovale, in the posterior part of the parietal lobe, and pressed upon the internal capsule below it. Beyond a moderate distension of the lateral ventricles the other parts of the cerebrum, the cerebellum, the pons, the membranes, and the vessels were healthy. Both internal and middle ears, the mastoids, the ethmoidal and frontal sinuses, and the throat and nares were healthy, and after a careful search the source of infection remained undetermined.

CASE 2.—The patient was a female, aged 24 years. With the exception of an attack of influenza two years previously she had always enjoyed good health. Her mental condition was very obscured on admission to the hospital, so that it was doubtful how far her statements could be trusted, but she gave a vague account of a discharge of matter from the left nostril at some previous time; this was not confirmed by her relatives. She had never had any ear trouble. 14 days before admission the patient was in her usual health, and whilst wiping some crockery she was suddenly taken with severe pain over the left eye, followed soon by swelling of the left side of the face. On the next day the pain was worse and she vomited several times. There was then an intermission of three days, after which the pain returned, and since then she had been confined to bed with intense left frontal headache, photophobia, repeated attacks of vomiting irrespectively of food, occasional diplopia, flushing of the face, stiffness of the neck and pains along the spine, with a thick feeling in the throat, and latterly incontinence of urine. On admission to hospital on Oct. 9th, 1905, she looked heavy and dull and her face was flushed. She was drowsy and apathetic and took no notice of her surroundings. The pulse was 62 and regular, the respirations were 20, and the temperature was 97·4° F. The tongue was furred. She vomited three times on the day after admission, after which the vomiting ceased. There were intense frontal headache and extreme tenderness over the left frontal region and over the left orbital plate. Mr. J. L. Firth kindly made a nasal examination, so far as the patient's condition would allow it, but found no other evidence of disease than the presence of some dried flakes of pus on the mucous membrane of the left nostril. There were no paralysis of the face or limbs and no affection of sensation, neither was there tremor of either limb. There were slight retraction of the head and stiffness at the back of the neck, with tenderness over the upper part of the spine. There was marked photophobia. The pupils were small; the left was larger than the right and both reacted to light and to accommodation. There was commencing optic neuritis most marked on the left side. No nystagmus, no deviation of the eyeballs, and no paralysis of oculo-motor nerves could be made out, although the patient occasionally said she saw double. The knee-jerks and ankle-jerks were exaggerated but equal on both sides. The plantar reflex was doubtful (? extensor). There was some rigidity about the knee and elbow-joints. Except for feebleness of the breath-sounds the thoracic and abdominal organs were normal. The urine (specific gravity 1020) contained a trace of albumin but no sugar or deposit. The abdomen was not retracted. A lumbar puncture gave a negative result. The ears were healthy and no pus could be detected in the nares.

On the next day, after a restless night with much tossing from side to side, the patient was more heavy and drowsy. The temperature was 97·4° and the pulse was 60. She lay on her back with her face turned to the left, took no notice of her surroundings, but answered when spoken to loudly. There was constipation but incontinence of urine. There were no fresh symptoms. On the 11th the drowsiness had increased still further. The pulse was 60 and the respirations were 16. The arms were rigid on attempted movement. On the evening of this day she had several attacks of complete unconsciousness for from 10 to 12 minutes, with stertorous breathing. The arms became rigid, and as each attack passed off the patient repeatedly raised her left arm, and rubbed the tip of her nose. During these attacks the pupils were fixed, the right contracting and the left dilating. On return of consciousness the right pupil dilated until they were both the same size. The eyeballs moved slowly to the left from the middle line. The temperature rose after these attacks to 98·2°. She passed into deep coma and died early on Oct. 12th. In the state of mental hebetude in which the patient remained after admission to hospital no accurate observations as to smell and taste could be made. She was not deaf.

Post mortem, except for some hypostatic congestion of the lungs and congestion of the kidneys, the thoracic and abdominal organs were normal. On opening the skull the dura mater was normal; over the vertex of the brain the pia-arachnoid was dry, the convolutions were flattened, and the sulci were partly obliterated; this was especially the case on the left hemisphere. The longitudinal sinus contained no clot. At the base of the brain there was suppurative meningitis, there being a thin layer of pus on the under surface of the cerebellum, around the medulla, and within the circle of Willis, whilst over portions of the basal surface a thin layer of lymph was seen. The left frontal lobe bulged somewhat and on incising it an abscess, of the size of a small hen's egg, containing bright yellow pus, and having a wall only moderately firm, was found in its anterior part over the orbital plate and about three-quarters of an inch from the anterior extremity of the lobe. The left lateral sinus contained firm ante-mortem clot; the right was empty. There was a small amount of bright yellow pus in the left frontal sinus; the remaining sinuses contained no pus. All other parts of the brain were healthy and both internal and middle ears were normal. A bacteriological examination of the pus was made, but the record of it has unfortunately been mislaid.

In the first of these cases there were no means of arriving at the exact position of the lesion giving rise to hemiplegia nor of ascertaining its nature. The first onset of symptoms was abrupt, taking place during one night, and the hemiplegia became complete in three days, and the whole duration of illness was 12 days. In the absence of heart and of kidney disease a vascular lesion, such as embolism or hæmorrhage, was improbable at the patient's age. The characteristic signs of intracranial abscess were conspicuously absent and none of the usual causes of this affection were present. Looking back upon the history of frequent colds in the head during the preceding three years, it seems possible that infection might have occurred through the nose, but there was no evidence of any such source of infection post mortem. The most probable diagnosis during the illness seemed to be that of tumour, which had remained latent, and then suddenly given rise to symptoms, possibly through the intermediary of hæmorrhage into its substance, such as sometimes occurs in a glioma. Against this hypothesis, however, was the absence of optic neuritis. As there were no localising indications further than that the lesion, whatever its nature, was on the left side of the brain, no attempt at relief by operation was feasible.

In the second case, on the other hand, the diagnosis of an intracranial abscess could be readily made from the presence of the characteristic signs, and the mental symptoms, site of pain and local tenderness, with evidence of a source of infection in the nose, pointed further to the localisation of the abscess in the left frontal lobe. But it was also considered on duly weighing the other signs present in the case, and also from the general condition of the patient, that she was further suffering from a complicating meningitis which precluded any chance of successful interference. In fact, it was obviously too late when she came into the hospital to do anything for her relief.

In conclusion, the first case is a good example of that form of cerebral abscess, chronic in character, which remains latent until the end, and the second emphasises the importance of dealing with the acute form of abscess at the earliest possible moment before necessarily fatal complications have arisen.

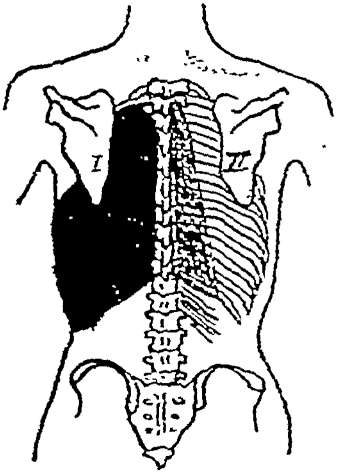
Bristol.

GROCCO'S TRIANGLE: PHYSICAL AND ANATOMICAL EXPLANATION.

BY F. W. FORBES-ROSS, M.D. EDIN., F.R.C.S. ENG.

IN pleurisy, with effusion into either pleural cavity, there has been described, particularly by Dr. W. Ewart among others in this country, as a phenomenon accompanying that affection an area of comparative (or relative) dulness along the spine on the side opposite to the effusion, having the shape of an elongated triangle, bearing a definite relative height to the height of the effusion in the affected side. This is especially the case if the patient is examined when in the sitting or standing posture. Although the upper outline of dulness in the affected side is that of a dome, with its highest point in the scapular line (posteriorly), falling away in either direction towards the spinal and axillary margins, yet the height of Grocco's triangle is always that of the height of the dome at its highest point. The *base* of Grocco's triangle being at the twelfth rib or thereabout is for the most part invariable in its lateral extension, varying very slightly in relation to the height of the triangle and of the effusion into the diseased side of the chest; in other words, not as much as would preclude an anatomical explanation of the phenomenon, inasmuch as a small effusion cannot dampen resonance of the opposite side so easily as a large effusion. The shape of the upper border of the effusion on the diseased side is also anatomically interesting. The height of the dome at the highest point is due to the shape of the chest and the convex lung surface at the area where it is highest —*that is, a thin* layer of fluid tends to creep up by capillary attraction. The fall towards the spine is due to the fact that the column of fluid in the corner formed by the vertebral column and ribs behind and the lung and posterior mediastinal wall in front and on the median line tends to sag or drop owing to its relative thickness. It is this thick column of fluid which acts as conductor *and transmitter of resonance-dampening* across the middle line. This sagging does not prevent the fluid conduction (or rather the *deadening* of resonance by damping-down of the resonance of the sound side) by means of the bones and muscular structures *acting as a solid medium* in consonance with the fluid on the diseased side to the full height of the dome on the diseased side. The result is that the height of Grocco's triangle is physically *consonant* with that of the height of the dome on the *diseased* side. (See *Fig.* 1.) The column already described is thicker below than above, *owing* to the fact that the costo-vertebral recess within the thorax is deeper below and gradually shallows as it ascends and so thins off the aforesaid column of fluid. For the same reason the very existence of Grocco's triangle becomes explainable and tolerably certain from a physical and anatomical basis alone. The relative dulness of Grocco's triangle *is due to* the underlying sound lung of the unaffected side imparting its resonance to and partially removing the bone- and muscle-conducted dampening of resonance of the fluid on the affected side.

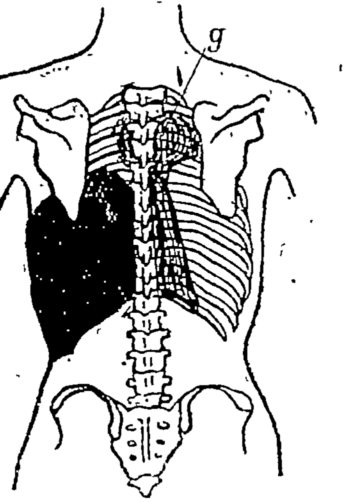
FIG. 1.



Black area is effusion dulness (I) and shaded area (II) Grocco's triangle.

Why is Grocco's area a triangle? Because the paravertebral groove or sulcus outside the chest is *widest* and *deepest below* and *narrows* and *shallows as it ascends* towards the seventh cervical spine, and the posterior mediastinum inside the chest is *widest* at its *upper part*, where it joins the superior mediastinum. The sound lung is therefore able to impart its resonance more and more to the *sound side* and nearer to the vertebral column, as the dull area ascends, owing to there being less and less muscular tissues *to* conduct the fluid-dampening of resonance passing from the diseased side across the *middle* line. Is there ever an exception to this? Yes, when in incipient cases of tuberculosis of lung there are enlarged bronchial glands in the posterior mediastinum and a pleural effusion occurs on the left side of the chest, Grocco's triangle on the right will suddenly spread at the upper part till it reaches the inner border *of the* scapula on the right side and is lost under the right scapula. This proves the contention that Grocco's triangle is due to the conduction by solid tissues of the fluid-dampening of resonance from the diseased to the sound side. In other words, from the sternum right round the diseased side to the spinal column and across the middle line is one continuous "resonance-dampening" block. It may be mentioned in passing that enlarged glands in the (upper) posterior mediastinum lie mostly to the right of the middle line in the interscapular space. (See Fig. 2.)

FIG. 2.

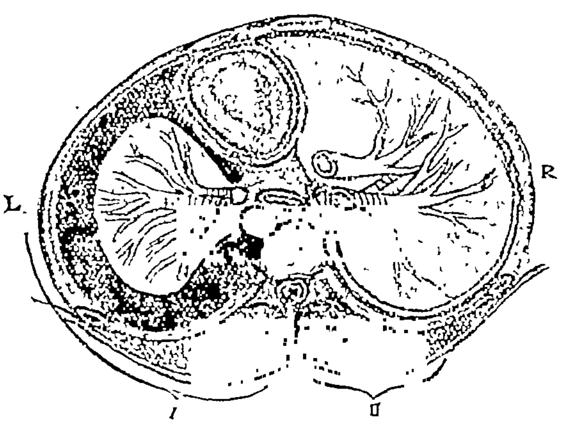


Grocco's triangle merging above into (g) gland dulness.

Grocco's triangle is not invariably present in all fluid effusions into the chest. Why is this? In some empyemata, such as are loculated and in demarcated pleural abscesses and effusions, the fluid media do not extend to the middle line posteriorly owing to adhesion of the pleural surfaces in that situation. There can in these cases be *no* trans-spinal conduction of resonance dampening. Even in some of these cases, however, the chest wall will conduct "resonance-dampening" to the spinal column and superincumbent muscles in a very slight degree. When an abscess or large empyema *extends to the spinal column*, then Grocco's triangle *is present*, with the same physical and anatomical signs and limitations, altered, however, by enlarged glands if present on the right side as before described. The above goes far to prove the anatomical causation of Grocco's area. The following rough drawings (diagrammatic) of cross sections of the chest will explain.

Fig. 3, representing a cross section at the mid part of the thorax (cardiac apex) shows a *wide* and *deep paravertebral grove* containing the massive spinalis and longissimus dorsi muscles, relatively *larger* bony vertebræ, projecting spinous processes, and adjacent ribs. The mass of hard and soft tissues from side to side and from before backwards is greatest at this point, as well as the mass and cubic capacity of the "costo-vertebral cavum" within the thorax. It can at once be seen that the combination of fluid and solid tissues will exert a considerable "resonance-dampening" influence across the middle line on to the sound side; hence the *base* of Grocco's triangle is *wider here than at any point above* the line of section, as higher up all the factors tend to diminish.

FIG. 3.

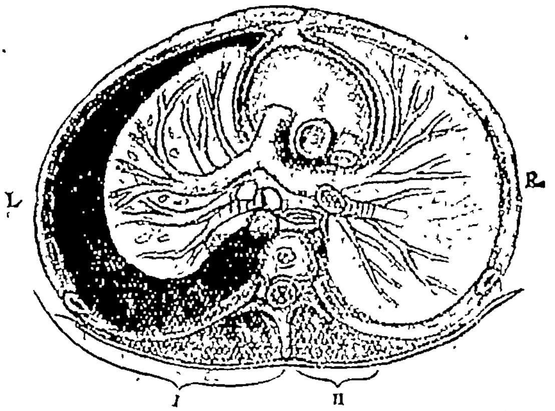


Section through apex of heart. I, Area of effusion dulness. II, Grocco's triangle.

Fundamentally the foregoing is correct; but the eleventh and twelfth ribs (and to a less degree the tenth), owing to their distal ends being practically free, do not vibrate in consonance with the rest of the chest wall and so tend to still further widen the dull *base* of Grocco's triangle outwards. This impairment, to a less degree, will be noticed on both sides in normal chests (not shown in Figs. 1 and 2).

Fig. 4 shows a section just at or above the level of the base of the heart. The paravertebral sulcus is *shallow*, the vertebræ are *smaller*, their spinous processes slant downwards, the muscular tissue is less and more spread out laterally, thus making the posterior chest wall more homogeneous as regards its lateral thickness; the costo-vertebral cavum within the thorax does not hold so much fluid as that below, therefore the resonance-dampening area approaches nearer the middle line, and so Grocco's triangle tends to *narrow to an apex* as it ascends the spinal column. It can easily be understood, however, that the larger the effusion into the diseased side the greater the physical "resonance-dampening" on the sound side and *vice versâ*. If also there be enlarged glands on the right side of the upper part of the posterior mediastinum then Grocco's area will spread out at the upper part after temporarily narrowing (see Fig. 2).

FIG. 4.



Section through thorax at base of heart. I, Area of effusion dulness. II, Tapering apex of Grocco's triangle.

As a surgeon my apologies are due to the medical section of the profession for presuming to explain physical signs in the chest, but my excuse and plea must be that my surgical interest in empyemata and other collections of fluid in the chest has seduced me from a befitting reticence. I offer the above explanation for what it is worth from a purely anatomical and physical standpoint clinically verified. Grocco's triangle accompanying pleural effusion is a physical necessity of the anatomical conformation of the posterior chest-wall.

Harley-street, W.

THE LOSS OF THE TENDO ACHILLIS REFLEX AND ITS DIAGNOSTIC VALUE IN "ALCOHOLIC" FAILURE OF THE HEART.

BY R. T. WILLIAMSON, M.D. LOND., F.R.C.P. LOND.,
ASSISTANT PHYSICIAN, ROYAL INFIRMARY; AND LECTURER IN MEDICINE, VICTORIA UNIVERSITY, MANCHESTER.

A CLINICAL form of cardiac disease is not infrequently met with, at least in South Lancashire, which is due to the drinking of large quantities of beer or spirits. The disease is a form of cardiac muscle failure and has been termed alcoholic dilatation of the heart and alcoholic heart failure. It has been very thoroughly and carefully described by Dr. Graham Steell[1] and by other writers in England and on the continent.

I do not propose in this article to consider the exact cause of the affection, whether it is due to the alcohol of beer and spirits, or to some impurity, or, in certain cases, to arsenic, which was found by Dr. E. S. Reynolds a few years ago in the beer sold in Manchester and proved by him to be the cause of an epidemic of peripheral neuritis. I wish in this note to refer simply to one sign which I believe to be of some value in the diagnosis of alcoholic failure of the heart from other forms of cardiac muscle failure. In cases in which shortness of breath, œdema, and other signs of cardiac failure are present the diagnosis of alcoholic heart failure is based chiefly on (1) the history and evidences of alcoholism; (2) on the absence of indications of valvular cardiac disease; (3) on the absence of nephritis; and (4) on the absence of indications of other known causes of cardiac muscle failure. Several peculiarities in the symptoms have been pointed out by Dr. Steell. In the diagnosis of alcoholic heart failure with secondary albuminuria from chronic nephritis with secondary cardiac failure I would emphasise the importance of ophthalmoscopic examination, since the detection of albuminuric retinitis would indicate the latter diagnosis. (To the writings of Dr. Steell the reader may be referred for an account of the diagnosis of alcoholic heart failure.)

---

[1] Medical Chronicle, April, 1893.

A definite history of alcoholic excess is often difficult to obtain in private patients and especially in females, and hence other evidences of alcoholism are of value in the diagnosis. The knee-jerks are lost in some cases of alcoholic heart failure, but I soon found that the proportion of such cases was too small for the sign to be of any diagnostic value. Loss of the tendo Achillis reflex is one of the first signs of the injurious action of alcoholic beverages on the peripheral nervous system and this reflex is often lost long before the knee-jerk. As it appeared probable that in this sign we should have an indication of diagnostic value I have carefully examined the condition of the tendo Achillis jerks in 21 cases of alcoholic heart failure and in many cases of heart disease which have not been caused by alcoholism. In making the examination I have used a *heavy* percussion hammer. The following are the results which I have obtained:—

21 Cases of Alcoholic Heart Failure.

	Tendo Achillis jerks.		Knee-jerks.	
18 cases with well-marked symptoms ...	Both lost ...	16 cases	Present... ...	10 cases.
			Lost	6 ,,
	One lost and one present	2 ,,	One present and one lost	1 ,,
			Both present	1 case.
3 cases with slight symptoms	Both present		Both present.	

In these cases paralysis was absent and there were no signs of neuritis beyond loss of reflexes, pains in the legs, and muscular tenderness. The two latter symptoms were often very slight or absent.

100 Cases of Cardiac Disease not due to Alcoholism (Valvular diseases, and dilatation or muscle failure not due to alcoholism).

	Tendo Achillis jerks.	
100 cases	Present	93 cases.
	Lost	2 ,,

In the two cases of non alcoholic heart disease in which the tendo Achillis jerks were lost the knee-jerks were absent and there was the Argyll-Robertson pupil. Both were cases of aortic valvular disease and there can be little doubt that the loss of the tendo Achillis jerks and knee-jerks and the Argyll-Robertson pupils were all due to commencing tabes dorsalis.

These observations demonstrate, therefore, that in cases of heart disease not due to alcoholism the tendo Achillis jerks were present in all cases except two, and in these two cases the loss of these reflexes was almost certainly due to early tabes. On the other hand, in *alcoholic* heart failure the tendo Achillis jerks were lost on both sides in 16 out of 21 cases, on one side in two other cases; they were both present in only three cases. In these three cases the symptoms were slight and the diagnosis not quite certain. Hence we may say that the tendo Achillis jerks are present in non-alcoholic heart disease unless there is some nervous complication, but are usually absent in alcoholic heart failure if the symptoms are well marked and if œdema and dyspnœa are both present (i.e., absent in alcoholic heart failure on both sides in 76 per cent. of cases, on one or both sides in 85 per cent.).

There are, of course, individuals who can take very large quantities of alcohol without either cardiac failure or loss of the tendo Achillis jerk occurring. Hence it is the absence of this reflex which is of chief value in diagnosis as one indication of alcoholic excess.

The loss of the tendo Achillis jerks in alcoholic heart failure is probably due to very early neuritis. It is not due to the œdema of the leg, since these reflexes may be obtained in non-alcoholic cases when there is marked œdema.

Probably the tendo Achillis reflex is always present in health. Under the age of 50 years it is generally admitted that the reflex is always present in the normal condition, but it was stated a few years ago that after the age of 50 years it was sometimes absent. Some observers have found, however, that both over and under 50 years of age the tendo Achillis jerk is always present in health. This has been my own experience. But in order to obtain evidence on this point I have recently examined the tendo Achillis jerk in 100 individuals over the age of 50 years who were either in good health or not suffering from any affection of the nervous system. The reflexes were present in all of the 100 cases.

It is to be remembered that the tendo Achillis jerk is often lost in diabetes mellitus[2] and after diphtheria. In both of these conditions cardiac failure may occur, but the history in the latter affection and the condition of the urine in the former are diagnostic. In lesions of the lower part of the spinal cord and of the cauda equina this reflex may disappear on both sides and in severe sciatica on one side (the side of the pain).

From the facts just recorded I think we may conclude that under certain conditions the tendo Achillis reflex may be of service in the differential diagnosis of alcoholic heart failure, but we should first exclude diabetes mellitus, diphtheria, and tabes as causes of the loss of the tendo Achillis jerks. Providing there is no glycosuria, no evidence of a recent attack of diphtheria, no sign of lesion of the spinal cord or cauda equina, and providing the pupils react to light and that there are no lightning pains or other signs of tabes dorsalis, then the loss of the tendo Achillis jerk is of value in diagnosis as a confirmatory sign that the alcoholic beverages taken have had an injurious action on the system—i.e., that they have produced one of the first signs of their toxic action on the peripheral nerves. (It is interesting to note that there were no signs of peripheral neuritis in any of the 21 cases examined beyond the loss of reflexes and in some cases aching pains and tenderness in the legs.)

The Argyll-Robertson pupil is practically never produced by alcoholism, but it is found in most cases of tabes. Hence the pupils should always be tested before attaching importance to the loss of the tendo Achillis jerk.

In a case of heart failure, in which, from the symptoms and signs, alcoholism appears to be a possible cause, the *loss* of the tendo Achillis reflex would be strongly in favour of this view, if we can exclude the other affection, just mentioned, which produces loss of this reflex. If the symptoms of cardiac failure are well marked the *presence* of the tendo Achillis jerk would be a point against alcoholic heart failure. But if the symptoms of heart failure were slight then the presence of the tendo Achillis jerk would be of little diagnostic value.

Manchester.

A CASE OF SPLENIC ABSCESS.

BY REGINALD H. LUCY, M.B., C.M. EDIN., F.R.C.S. ENG.,

SURGEON TO THE SOUTH DEVON HOSPITAL, PLYMOUTH; CONSULTING SURGEON TO THE KINGSBRIDGE AND LISKEARD COTTAGE HOSPITAL.

ABSCESS of the spleen seems to be so rare in this country that the following instance may prove of interest.

On Nov. 17th, 1906, I was asked by Mr. S. G. Vinter of Torpoint to see a married woman, aged 23 years. She had been delivered with forceps of her first child, a boy, after an eight hours' labour, on Oct. 14th, 1906. The perineum was not torn, but the placenta being firmly adherent was removed piecemeal, leaving a rough, shreddy surface. A lysol douche was given immediately afterwards and on each succeeding day. On the fifth evening post partum the temperature ran up to 104·4° F., followed on the thirteenth evening by two severe rigors, recurring the two succeeding days, while on the seventeenth morning the temperature fell to 98° and the pulse to 84, which was accompanied by a profound rigor, lasting half an hour. The temperature again rose to 104·6° and oscillated violently.

---

[2] R. T. Williamson: Review of Neurology and Psychiatry, October, 1903.

On the evening of the twenty-second day 20 cubic centimetres of antistreptococcic serum were given per rectum, repeated next day, and again on the twenty-seventh, thirtieth, and thirty-fourth to thirty-ninth days. During this time the pulse-rate varied between 100 and 130 per minute with profuse sweating and occasional vomiting. On the thirty-fifth evening following delivery I found the abdomen distended, tympanitic, and tender, more especially in the left hypochondrium, where a hard lump could be felt, moving slightly on respiration and exhibiting the characteristic notch on its anterior border. Being uncertain as to the presence of pus in what was obviously the enlarged spleen and also whether that organ was adherent to the anterior parietes or not I advised the continuance of the antistreptococcic (polyvalent) serum. This was given daily until the forty-first day, when I saw her again with Mr. Vinter and his partner, Mr. R. J. Percy Thomas. The spleen had increased in size; it no longer moved on respiration, but still retained its notched border and the parietes superjacent were slightly reddened and œdematous.

Under chloroform a three-inch vertical incision was made along the centre of the left rectus sheath; the areolar tissue was found to be œdematous and on pushing a pair of sinus forceps through the peritoneum a quantity of horribly foul-smelling pus of a dirty yellow colour, mixed with greyish-purple sloughs of splenic tissue, escaped. A large rubber drain-tube was passed into the cavity of the spleen and stitched to the skin incision. The temperature rapidly fell and in 48 hours was normal and remained so during convalescence, while the pulse-rate soon reached 84. The number and bulk of sloughs that came away were extraordinary, but very little bleeding occurred. The cavity closed at the end of three weeks.

The interesting features of this case seem to be: (1) the spleen was the only organ or part affected; (2) though swollen it never lost its characteristic outline, but ceased to move on respiration; and (3) the large amount of splenic tissue lost in the form of sloughs and yet there are now (May, 1907) no apparent blood changes. I regret that no microscopical or bacteriological examination of the discharge was made, but the stench was so overpowering that a specimen would have nauseated even the most hardened pathologist.

With regard to the pathology of this case it is probable that septic thrombosis of the veins at the placental site took place and from there an embolus was carried through the heart and pulmonary circulation into a branch of the splenic [illegible]. As throwing a light on the reason why the spleen became the "seat of election" for infective embolism and infarction, a history was given that three weeks previously to the birth of her boy the patient fell from a table, striking the left side of her chest so violently across the back of a Windsor chair that the latter was broken by the force of her impact. It is therefore probable that a hæmatoma was caused in or around the spleen which subsequently became infected in the manner above outlined.[1] The patient has never resided abroad nor suffered from enteric or other fever, nor had she valvular disease of the heart. Abscess of the spleen occurs in the tropics during malaria or yellow fever, also in the course of enteric fever, septicæmia, pyæmia, and particularly in ulcerative endocarditis.

The following references in recent medical literature are appended. 1. Nolan,[2] in describing a case of abscess of the spleen, states that only five successful results are recorded after operation. His case is very similar to the one I have just described. A woman, aged 25 years, six weeks after confinement became ill and feverish. Enteric fever was suspected. Sudden acute pain in the left side was followed by dyspnœa and a pleuritic effusion was found, together with a greatly enlarged but *not* tender spleen. A vertical incision along the left linea semilunaris was made; a cavity was reached from which about a litre of dull brown pus, with a faintly sweet smell, escaped. The peritoneal cavity was not opened. The wound was plugged with gauze and uninterrupted recovery followed. It is doubtful whether this patient suffered from enteric fever or whether the abscess followed puerperal infection; in either case an infective embolus would be the proximate cause. This paper is referred to in the *British Medical Journal Epitome*, April 14th, 1894, para. 295, and also quoted by Mayo Robson in the *Medical Annual* for 1895, p. 453. 2. Black.[3] The patient was a sailor, aged 21 years, who two years previously had contracted yellow fever; the tumour was incised yielding three and a half pints of bluish yellow pus; the cavity was plugged and healed by granulation after secondary suture with complete recovery. 3. Mayo Robson in the *Medical Annual* for 1904, p. 651, refers to a case reported by Dr. G. Riolo in the *Riforma Medica* of April 24th, 1902, of a splenic abscess complicating malaria successfully treated by incision and drainage. 3, 4, and 5. Mr. Robson also refers to a case under his own care and cites a paper by Dr. A. L. Staveley in the *Annals of Surgery* for June, 1903, on Splenic Infection, reporting two successful operations. 6. Harrington[4] reports two cases both following typhoid fever. 7. Moynihan[5] refers to seven cases of splenic abscess treated by operation up to 1900 and three cases recorded since by Murphy, Karewski, and Eberhart.

With regard to the treatment it appears to me better to wait until adhesions to the anterior parietes have formed and then perform splenotomy with drainage rather than traverse the unguarded general peritoneal cavity to undertake splenectomy, an operation sufficiently severe in an uninfected patient with its amount of shock and risks of hæmorrhage, immediate and remote.

Plymouth.

RICE AND BERI-BERI:

PRELIMINARY REPORT ON AN EXPERIMENT CONDUCTED AT THE KUALA LUMPUR LUNATIC ASYLUM.

BY WILLIAM FLETCHER, B.A., M.B., B.C. CANTAB.,
DISTRICT SURGEON, KUALA LUMPUR, FEDERATED MALAY STATES.

DURING the year 1905 an epidemic of beri-beri broke out in the Kuala Lumpur Lunatic Asylum. Commencing in February, it reached its height in July and August, declining somewhat towards the end of December. Out of 219 lunatics treated in the asylum during the year 94 persons were affected, of whom 27 succumbed to the disease. The chief constituent of the rations supplied to the inmates of the asylum was uncured (Siamese) rice, and in view of the fact pointed out by Dr. Braddon that beri-beri occurs chiefly amongst communities with whom such rice is the staple article of diet it was decided, with the sanction of the Government, to place half the lunatics on cured (Indian) rice. The Government readily gave its consent and the experiment was commenced on Dec. 5th, 1905. The result up to Dec. 31st, 1906 (i.e., one year and 26 days) was that 34 out of 120 persons fed on uncured rice suffered from beri-beri and 18 died, whilst among 123 patients dieted on cured rice there were no deaths from beri-beri and only two cases, both of whom were suffering from the disease on their admission to the asylum.

1. By uncured rice is meant the ordinary white rice, sold in the Federated Malay States as Rangoon or Siam rice, which is eaten by all classes except Indians and Malays. This rice after being harvested is taken to the mills, where it is husked and cleaned before being sold to the rice merchants. Cured rice is brownish in colour and forms the staple of diet of Indians and Ceylonese. The great difference between this rice and the uncured variety is that the former is boiled and dried before being milled. The Malays keep their rice stored unhusked and pound and winnow it when they wish to cook it. A. White rice is stored unboiled after being husked. B. Cured rice is stored after being boiled and then husked. C. Native Malay rice is stored unhusked. Except for the difference in the rice the two parties—those on cured and those on uncured rice—received the same kind and the same amount of rations. Excepting the rice the food-stuffs for all patients were prepared together in the same kitchen and cooked in the same cooking pots.

2. The lunatics are housed in two exactly similar buildings on opposite sides of a quadrangle surrounded by a high wall. On Dec. 5th all the lunatics at that time in the hospital were drawn up in the dining shed and numbered off from the left. The odd numbers were subsequently domiciled in the ward on the east side of the courtyard and no alteration was made in their diet, they were still supplied with the same

---

uncured rice (Siamese) as in 1905. The even numbers were quartered in the ward on the west of the quadrangle and received the same rations as the occupants of the other ward, with the exception that they were supplied with cured (Indian) rice instead of the uncured Siamese variety. The following is the ordinary diet scale of the lunatic asylum: fresh meat, four ounces four times a week; fresh fish, 5½ ounces two times a week; salt fish, 5½ ounces once a week; vegetables, eight ounces daily; curry stuffs, 1½ ounces daily; and cocoanut oil, ¼ of an ounce daily. Uncooked rice: Siam, 28 ounces to be supplied as per sample for uncured rice ward; Bengal, 28 ounces to be supplied as per sample for cured rice ward. At the commencement of the experiment all patients showing unmistakeable symptoms of beri-beri were removed to the district hospital, which is two miles distant from the asylum. On Dec. 5th there were 59 lunatics in the asylum; of these 29 were put on cured rice and 30 on Siamese rice. The next patient admitted to the asylum was admitted to the Bengal rice ward, and the one admitted after him to the uncured rice ward, the next to cured, and so on alternately to the end of the year.

3. The knee-jerks of all patients in the asylum on Dec. 5th, 1905, were noted on that date and of those admitted subsequently on the dates of their admission. The presence or absence of œdema was noted at the same time.

Patients admitted to Siamese (Uncured) Rice Ward.

Knee-jerks average	... ...	35	(21 developed beri-beri).

„ absent	25*
„ impaired	2
„ increased	5
„ „	6
„ „	3

* Two had beri-beri on admission.

32 patients in the Bengal rice ward had some œdema on admission.

4. By June 20th many cases of beri-beri had occurred amongst the patients in the east ward who were eating uncured rice, whereas no cases had occurred in the west ward, the inmates of which were dieted on cured (Indian) rice.

5. In view of the theory so strongly advocated by Sir Patrick Manson that beri-beri is a place disease, it was thought possible that the east ward was infected. Therefore on June 20th the patients were transposed, those on uncured rice being moved to the west ward and those on cured (Indian) rice transferred to the east. From June 20th to Dec. 31st no beri-beri developed amongst the patients on cured rice although they were living in a ward where beri-beri had been rife amongst the lunatics who were fed on uncured (Siamese) rice.

6. From Nov. 3rd, 1905, until April 11th, 1906, all persons showing symptoms of beri-beri were transferred to the district hospital, as it was considered that this would be beneficial to those suffering from this disease and also might possibly prevent the spread of it within the institution. In all 13 persons suffering from beri-beri were sent to the district hospital of whom nine died.

7. In April, as no patients on cured rice had developed beri-beri, it was thought that it might benefit those already suffering from the disease to withdraw them from the uncured rice diet and place them on the cured or Indian variety. Between April 11th and Dec. 31st ten cases of beri-beri were transferred to the ward occupied by patients on cured (Indian) rice and were supplied with that rice instead of the uncured variety which they had been taking when they developed the disease. All these ten patients recovered.

It is worthy of note that although patients actually suffering from beri-beri were put to live amongst the lunatics fed on cured rice none of the latter developed the disease. This, as far as it goes, is opposed to the theory of Dr. C. W. Daniels that beri-beri is a parasite disease, probably protozoal, conveyed by the agency of bugs or lice. Neither does the above result conform to Dr. Hamilton Wright's theory that beri-beri is an infectious disease communicated from patient to patient by means of the excreta. In this connexion it should be mentioned that in September, 1905, it was noticed that the lunatic asylum was infested with bugs, and at the suggestion of Dr. Daniels some of these were collected and put on monkeys, mice, and guinea-pigs. Lice from the head of a beri-beri patient were used in the same way. Later the bacteriologist made an emulsion of some bugs taken from the lunatic asylum and injected it beneath the skin of an orang-outang. None of the animals showed any signs of beri-beri. The bugs in the asylum were to a great extent got rid of before the commencement of 1906 by means of hot water, sun, perchloride of mercury, and tuba root, but they still are, and, I am told, always have been, present in the old building.

8. With regard to the general management of the lunatics, the two batches of patients are both fed in the same shed but at different times and at different tables, those patients on cured rice diet commencing their meal when the patients on Siamese rice have finished. The two batches of patients are only separated at night and when eating their meals; at other times they associate together in the courtyard and are employed outside the asylum in working parties. Those patients who were sane enough and strong enough physically to be employed in working outside the asylum, in the hospital grounds, or in the Guinea grass field opposite the asylum enjoyed no special immunity to beri-beri but suffered equally with those patients not so employed. 12 out of 34 persons affected with beri-beri belonged to the outdoor working party.

9. The uncured (Siamese) rice supplied to the asylum was of excellent quality (No. 1) and much better than that to which persons of the class from which the patients are drawn are accustomed outside the asylum. No mouldy or stale rice was given. The cured or Indian rice was of No. 1 quality. It was not Province, Siam, or Rangoon rice cured in Penang, but the small, round-grained Indian rice cured in India. The rice was cooked in the usual Eastern manner.

The following is the procedure. It is first washed with cold water in galvanised-iron buckets. It is then thrown into a shallow iron pan or kwali half full of hot water, which is placed over a wood fire. In about 20 minutes the rice has swelled and has taken up all the water (a little earlier in the case of the Siamese rice and later in the Indian variety). It is then stirred round twice with a large spoon or chabok and the burning wood is taken out from under the kwali, only glowing charcoal being left. When the rice has become soft, which occurs about 20 minutes later, the rice is taken out with a large spoon, care being taken not to disturb the thin sheet of burnt rice, or krak, which is caked over the surface of the kwali. The cake of burnt rice is afterwards scraped out and given to the fowls, pigs, &c. The two varieties of rice were both cooked in the same manner by the same cook (a Chinese). It is worthy of note that the culinary methods followed by Tamils and other consumers of cured rice differ slightly from the Chinese procedure. Tamils cook their rice with a larger proportion of water and when it commences to boil they pour off the supernatant fluid, whereas the Chinese allow the rice to take up all the water and pour none off. This is an important fact if the theoretical poison in rice which is supposed to cause beri-beri be soluble in water. Throughout the course of the experiment at the asylum a separate kwali, or cooking-pot, was used for each kind of rice and no uncured rice was cooked in the kwali set apart for the preparation of Bengal rice. Similarly different spoons, &c., were used for stirring each kind of rice and also for serving it out to the patients. Two sets of plates were provided, one for the patients on cured rice and another for the patients on Siamese.

10. It has already been mentioned that 10 patients who had been eating uncured rice and had developed beri-beri were transferred to the Bengal rice diet and recovered. The admission of these patients caused some overcrowding in the Bengal rice ward. Four men were therefore transferred from the cured rice ward and put on a diet of uncured rice. These men were not selected in any way, but the first four names on the Bengal rice list were taken. They were apparently healthy and had been on a diet of cured rice since

Dec. 5th, 1905. The following is a list of these four patients and the result of their transfer:—

No.	Name.	Transferred to uncured rice.	Result.
1	Salleh.	24/4/06	Remains healthy.
2	Foo Lim.	"	Developed beri-beri on 7/7/06. He had had beri-beri 10 months before.
3	Hee Chong	27/4/06	Developed œdema and some weakness.
4	Quai Kiam.	23/6/06	Developed beri beri 27/8/06 and died on 24/9/06.

No conclusion can be based on the above, the numbers are too small; but one cannot help being struck by the fact that 10 patients suffering from beri-beri transferred to Bengal (cured) rice all recovered, whereas of four apparently healthy men transferred from Bengal to Siamese (uncured) rice two developed beri-beri, one of whom died.

11. At the commencement of the experiment on Dec. 5th, 1905, there were 59 patients remaining in the asylum; 29 of these patients were placed on a diet of cured rice, whilst 30 remained on Siamese rice. From Dec. 5th, 1905, to Dec. 31st, 1906, 90 lunatics were admitted to the Siamese rice ward, 17 of them developed beri-beri; whilst of the 30 remaining on Dec. 5th 17 developed beri-beri before Dec. 31st, 1906. During the course of the experiment four lunatics were admitted to the asylum who were already suffering from beri-beri. They were admitted on the following dates: Dec. 10th, Jan. 23rd, March 19th, and June 5th. Two of them were put on Siamese and two on Bengal rice. The majority of the cases of beri-beri occurred amongst lunatics who had been in the asylum for a considerable time.

	Cases.
Cases suffering from beri-beri on admission	4
Cases occurring amongst lunatics during their first month in the asylum	6
Cases occurring amongst lunatics during their second month in the asylum	7
Cases occurring amongst lunatics during their third month in the asylum	8
Cases occurring amongst patients who had been in the asylum more than three months	20
Total	45

In all 36 persons suffered from beri-beri. One patient had three attacks and seven patients two attacks. 28 had one attack. Whether the eight patients who were attacked with beri-beri more than once during the experiment actually suffered from a fresh "infection" (if one may use the word in this connexion) or whether the subsequent attacks were of the nature of relapses it is impossible to say, owing to our lack of knowledge of the actual cause of the disease.

Of the 36 persons who suffered from beri-beri 16 died during their first attack; ten were transferred to the cured rice ward, and all recovered; of the ten patients who remained on Siam rice two were discharged from the asylum before being attacked a second time and eight had relapses.

Died during first attack	16
Transferred to Bengal ward during first attack and recovered without relapse	10
Discharged from asylum before being attacked a second time	2
Remaining on Siam rice and suffering from second or third attacks of beri-beri	8
Total	36

12. The mortality of the lunatics on either diet was much the same except with regard to beri-beri:—

Cause of death.	Number of deaths (Bengal rice).	Number of deaths (Siam rice).
Beri-beri	0	18
Mania	6	4
Other causes	4	2
Dysentery	11	11
Total	21	35

Summary.

13. *A.* Amongst 120 patients on uncured rice there were 43 cases of beri-beri (two admitted with the disease) and 18 deaths. Amongst 123 patients on cured rice there were two cases of beri-beri, and these both had the disease on admission. *B.* Ten lunatics actually suffering from beri-beri who were placed on a diet of cured rice all recovered. Of 26 patients suffering from beri-beri who were not put on a cured-rice diet 18 died. *C.* None of the ten lunatics suffering from beri-beri who were placed on a diet of cured rice had a relapse. Of the 26 patients suffering from beri-beri who were not transferred to a cured-rice diet 16 died during the first attack and the remaining ten all developed beri-beri again with the exception of two who were discharged, being no longer insane. The latter have been lost sight of and whether either of them subsequently relapsed is unknown. *D.* Four lunatics who had been on a diet of cured rice for more than five months and were apparently healthy were transferred to a diet of uncured rice. Two of these patients developed beri-beri within three months.

14. In an experiment of this nature the personal factor always comes in question. It may, therefore, not be out of place to state here that at the commencement of the experiment the opinion was held by myself that rice was neither directly nor indirectly the cause of beri-beri. It was fully expected that the patients on Bengal rice would suffer from beri-beri to the same extent as those who remained on the Siamese variety and that the result of the experiment would be a refutation of the rice theory. With this in view precautions were taken to provide separate cooking utensils, plates, &c., for each set of patients in order that the upholders of the rice theory might not be able to point to any possibility of contamination of the Bengal rice with the poison which is supposed to be present in uncured rice. Contrary to expectation, the result of the experiment, so far as it goes, is to prove the truth of Dr. Braddon's contention that uncured rice is the cause of beri-beri. It remains to be proved whether the cause of the disease amongst the eaters of uncured rice is a poison contained in the rice or whether there is something essential to the human economy which is supplied by the cured rice whilst it is absent in the uncured. Takaki and the Japanese school still hold that a deficiency of proteids in the diet is the cause of beri-beri. As yet it has, unfortunately, not been possible to obtain analysis of the two kinds of rice; but when this is done it will probably be found that the cured rice contains a larger quantity of proteid matter than the uncured. If this be the case the deficiency of proteid matter in the diet may be the actual cause of the disease, or, what is more likely, the lack of nutritive matter in the rice may induce a condition in the patient which renders him an easy prey to some external agency—bacterial or protozoal—which is the actual cause of beri-beri. It is well known that certain conditions of the body render it specially liable to the attacks of beri-beri—e.g., syphilis and the puerperium. In 1904 there were eight cases of beri-beri amongst women admitted to the General Hospital, Kuala Lumpur; all these occurred amongst women in the puerperal state.

Conclusions.

15. Uncured rice is, either directly or indirectly, a cause of beri-beri, the actual cause being either (1) a poison contained in the rice; (2) deficiency of proteid matter, the disease being due to nitrogen starvation; or (3) uncured rice does not form a sufficiently nutritive diet and renders the patient's system specially liable to invasion by a specific organism, which is the cause of beri-beri.

Postscript.—Throughout the course of the experiment no doubtful cases have been noted as beri-beri. Many cases of slight œdema, abnormal reflexes, &c., may have been of the nature of abortive attacks. The following record of an examination of the knee-jerks and of the presence or absence of œdema amongst the patients now in the asylum may be of interest. The examination was made on May 19th, 1907. The results were as follows: the knee-jerks *of* patients on Siam rice (May 19th, 1907): present, 13; absent 18 (in 5 absent on admission); increased, 6; total, 37. Knee-jerks of patients on Bengal rice (May 19th, 1907): present, 23; absent, 8 (in each case absent on admission); increased, 5; total, 36. With regard to œdema, patients on Siamese rice 10 out of 37 had it and patients on Bengal rice 4 out of 36. Sixteen of the 37 patients on Siamese rice were *admitted* to the asylum before the beginning of 1907 and *consequently* had been on this diet for a considerable period; in eight of these 16 cases the knee-jerk was absent and in three it was increased, while in five œdema was present. In all those eight cases on Bengal rice in which the knee-jerks were absent they were noted as being absent on admission. Three were cases which had been transferred to a Bengal rice diet after having developed beri-beri whilst on a Siam rice diet. Two had been treated for beri-beri in other hospitals. Two gave a history of previous attacks. In one case the cause of absence of reflex is unknown. Since the end of December, 1906, up to the present date (May 19th, 1907) 12 cases of beri-beri have developed amongst the patients on a Siamese uncured rice diet. No patients on Bengal (cured) rice have suffered from the disease. The 12 cases occurred as follows:—

During the first month of residence in asylum	0
During the second month " "	3
During the third month " "	4
After three months' residence in asylum	5
Relapse cases	0
Total	12

Thus from the commencement of the experiment in December, 1905 (excluding patients actually suffering from the disease on their admission to the asylum), there have been (41 + 12) 53 cases of beri-beri amongst the patients on Siamese rice and none amongst those on a Bengal rice diet.

Kuala Lumpur, Federated Malay States.

Medical Societies.

Society for the Study of Disease in Children.—The annual provincial meeting of this society was held on June 15th at Bedford, Dr. R. H. Coombs being in the chair.—Dr. C. O. Hawthorne opened a discussion on Acute Rheumatism in Childhood. He referred to the considerable change which had taken place in the professional view of the age incidence and to the special characters which distinguish the disease in childhood, especially the frequency of cardiac disease. This he attributed partly to the absence of restraint of the child's activities resulting from the comparative escape of the joints, and he advocated the practice of informing the parents of rheumatic families of the risks involved even in the apparently trivial illnesses of their children. He thought that there was too ready a tendency to apply the term "rheumatism" to isolated events, the nature and origin of which were obscure. He also discussed the curative and prophylactic treatment.—Dr. W. Ewart suggested that the glandular condition of early childhood was less prone to favour retardation in the joints and the child could rid himself of disease in the joints and it would find a seat elsewhere. He suggested calomel and antiphlogistic remedies in the treatment of endocarditis.—Dr. A. Morison referred to erythema nodosum, which, he said, was not limited to rheumatic subjects; it was generally preceded by tonsillitis at an interval of from 10 to 14 days. He looked upon this as its incubation period.—Dr. A. C. Hartley (Bedford) said that in that town, on the banks of a river, with a damp climate, it would be expected that rheumatism would be very common, but his experience of 14 years did not bear this out.—Dr. G. A. Sutherland thought that it was a mistake to prolong rest in bed after active endocarditis had passed away, which was frequently done owing to the reappearance of a murmur. He referred to cases of recurring subacute rheumatism where salicylates failed; he considered that there was some concealed source of infection which was not discovered.—Dr. E Cautley read a paper on Cerebro-spinal Meningitis. He mentioned the different varieties and their relative age incidence as an aid to diagnosis; also the relationship of the sporadic to the epidemic variety, the means of diagnosis, including lumbar puncture, &c.—Mr. A. H. Tubby read a paper on Contraction of the Tendo Achillis as a cause of the following symptoms: pains in the calves, shambling gait, sprained ankle, everted feet, turning in of the toes, &c. He said that the contraction of the calf muscles produced a lessening of the power of dorsiflexion of the foot and shortening of the stride in consequence. It was usually due to infantile paralysis and could be remedied by lengthening the tendon, the method of doing which was described.—Dr. H. Skelding described a case of Bilharzia in a boy, aged 11 years, who came from Rhodesia. The symptoms were great drowsiness and hæmaturia. The ova were found in the urine.—Dr. G. Harvey Goldsmith described a condition occurring in children to which he gave the name of "œdema of the limbus." There were photophobia and injection of the ocular conjunctiva, on which were small grey nodules that never broke down. It was rapidly cured by the yellow oxide of mercury ointment.—Clinical cases, pathological and microscopical specimens, and skiagrams were shown by Dr. Goldsmith, Dr. Ross, Dr. R. Coates, Dr. W. Phillips, Dr. H. L. Waller, Mr. Johnson, Mr. W. A. Sharpin, Mr. W. G. Nash, and Mr. G. T. Verry.

Bradford Medico-Chirurgical Society.—A meeting of this society was held on May 28th, Dr. A. Mantle, the President, being in the chair.—A paper was read by Dr. A. F. Martin entitled "A Study of Post-typhoid Pyrexia" in which an account was given of 13 cases of typhoid fever out of a total of 63 admitted to the North Staffordshire Infirmary in the year 1905 which developed post-typhoid fevers of other nature than a relapse. A review of the English and American literature of the subject was given, and a classification suggested by Delafield as a basis of study was adopted since it agreed with the findings of Dr. Martin in his cases. The important thing was to distinguish these fevers from relapses. Curschmann was quoted as insisting on the reappearance of some of the classical signs of the typhoid infection before a diagnosis of relapse could be arrived at. In the fevers in question these were absent. Of the three types which Delafield found to exist the first included all those rises of temperature which were slight and temporary. They usually occurred in those who were of a nervous introspective temperament and their only importance was to learn to disregard them. These and perhaps some others were of a purely nervous origin. In the second group the fever was of indefinite length, lasting from eight days to one month, developing early in convalescence, and was of a remitting type suggestive of chronic septicæmia. The general condition showed a progressive wasting and later cardiac weakness. Some were mild and others were very severe infections. The treatment adopted in checking the fever was as speedy a return to full diet as was consistent with safety. Salicylate of sodium was found to be of no avail. In one case fæcal accumulation had occurred before the onset of the secondary fever without any rise of temperature. The view held by Da Costa that constipation was a frequent cause of post-typhoid pyrexia did not receive support from this and other cases. The anæmic and the nervous origin of these fevers was discussed, but did not find strong support from observations made. In the third group the fever was similar in type but was accompanied by venous thrombosis. Hacker's statement was taken as evidence of their septic nature—namely, that in post-typhoid thrombosis pyogenic cocci were frequently found in the thrombus, whereas Eberth's bacillus typhosus had not been isolated. These thromboses occurred chiefly in those cases where the primary fever had been unusually lengthy, and the fever accompanying them was often severe and showed rigors. The treatment adopted was the same as in the previous group and it was found that salicylate treatment in some cases was beneficial and in others a course of antistreptococcic serum did good. There were six cases of this type, the last being a remarkable case of post-typhoid mitral endocarditis developing nine weeks after the primary fever had abated. It was argued from a similarity of the type of fever in Groups 2 and 3 that the second group could fairly be said to be of septic origin.

Reviews and Notices of Books.

George Buchanan: A Memorial 1506–1906. Contributions by various writers, compiled and edited by D. A. Millar. St. Andrews: W. C. Henderson and Son, University Press; London: David Nutt. 1907.

Just a year ago Scotland celebrated the fourth centenary of one of her forgotten worthies, George Buchanan, first at St. Andrews, of which he was an alumnus and afterwards principal; and, secondly, at Glasgow, in which university, as a west country Scot, he took special interest. Both celebrations were in the highest degree successful, evoking in favour of the "Humanism," of which he was a typical exemplar, a demonstration which must have been peculiarly reassuring to those who think humanistic study doomed to succumb before the forward movement of science. They afforded convincing proof that there need be no antagonism between the old learning and the new—both celebrations, indeed, owing initiative and support to men of the most varied interests, literary as well as scientific, belonging, moreover, to professions in which the medical was hardly less prominent than those of the Church and Bar.

The present volume is issued under the auspices of the Students' Representative Council of the University of St. Andrews, in whose behalf it has been edited by a distinguished member of that body, Mr. D. A. Millar, who has interpreted his duties in the largest and most liberal sense and given them practical effect with equal industry and skill. It is a *Festschrift* artistic in its exterior and exhaustive in its contents, contributed, as these have been, by some five-and-twenty experts in the departments covered by Buchanan's life-work, and resulting in an *ensemble* from which a full and faithful portrait of the man in his many-sided character and career can be drawn by every reader for himself.

First comes an Alcaic ode in 20 quatrains by Dr. J. P. Steele, of which the following may be given as a sketch of the romantic vicissitudes of Buchanan's life on the banks of the Seine or the Garonne, the Mondego or the Po, the Thames or the Forth, and the integrity of character that he maintained through them all:—

"Tu, sive potes Sequanam et Orbilii
Fungare duro munere; seu valens
Praelector ad latum Garumnam
Vasconidas renoves Athenas;

Seu Lusitanae de cathedra Scholae
Pulsus maligno crimine, carceris
Sub nocte prospectes in horas
Supplicium nece pejus ipsa;

Seu propter undas Eridani ducem
Gallum sequaris Palladaque inferas
In castra Mavortis, remixtis
Carminibus lituo strepenti;

Seu missus Aulae nuntius Anglicae,
Regisve doctor sis vigil alite
Nati sinistra; seu Supremo
Concilio moderere Cleri;

Tu semper idem, nec pede devio
Rectum relinquens, dotibus uteris
Sic mentis ut, vultu sereno,
Æquus eas per iniqua rerum."

Sir Archibald C. Lawrie follows with a luminous paper on Buchanan's progeniture and then comes a pleasantly written account of his "Early Surroundings and Associations," by the Rev. R. Munro. "Buchanan's Student Days" is the theme of the next chapter, by Mr. W. Bayne, lecturer in English at the University of St. Andrews; "Buchanan and Continental Thought" forms the next contribution from the highly competent pen of Principal Lindsay of the United Free Church College, Glasgow; and a bright essay in French on "Buchanan à Bordeaux" comes from the Latin professor at that seat of learning, M. H. de la Ville de Mirmont. This is followed by other papers, all bearing on the life and work of Buchanan, papers among which may be signalised those of Senhor G. J. C. Henriques, legal adviser to the British Embassy at Lisbon, on "Buchanan in Portugal"—a most interesting paper for the light which it throws (*inter alia*) on the methods of the Inquisition; of Mr. A. H. Millar, who gives an impartial account of the great humanist's relations with Mary Stuart; of Dr. Mackinnon of St. Andrews, on "Buchanan as a Political Philosopher"; of Mr. Munro on "Humanism and Science," *à propos* of Buchanan's great poem, so much admired by Hallam, "De Sphaerâ"; of Mr. Maitland Anderson on the Bibliography and Portraits of Buchanan (two admirable contributions); and of Miss L. P. S. Hutton, who discourses with acuteness and *brio* on "The Humanist: a Psychological Study." The editor's elaborate paper on "Buchanan Memorials" winds up the list of original contributions, followed by an epilogue in English verse addressed to George Buchanan by the Rev. A. Brown—a composition worthy of the best translator of Buchanan's "Sacred Dramas."

The second half of the volume contains specimens of Buchanan's poems in the Latin original, with translations into English and French contributed by the successful competitors at St. Andrews, Paris, and Bordeaux respectively for the prizes given for these translations by Dr. Steele. These are of various merit, the French renderings of Buchanan's magnificent ode on the Taking of Calais, by M. Bonnerie and M. Pettimangin of Paris, worthily dividing the palm with "Father Prout's" animated version, which is printed between them. Bordeaux also appears to advantage in M. de la Vaissière de Lavergne's translation of the famous Sapphic ode, "Ad Juventutem Burdigalensem," which, too, is effectively reproduced in English by Mr. Lionel S. Charles of the University of St. Andrews. Mr. T. D. Robb, the winner of the prize (value £105) for an essay on "Sixteenth Century Humanism as illustrated by the Life and Work of George Buchanan," translates with much felicity the elegiacs in which Buchanan depicts the wretched condition of the teaching profession in the Paris of his day and also the noble sonnet addressed by the great "humanist and reformer" to the good and accomplished Archbishop of Glasgow, Gavin Dunbar. Nine appendices appear at the end of the volume, the last one giving a full report of the quatercentenary celebration, with Lord Reay's "Oraison de Circonstance" (a masterly performance), and the banquet which closed the day, at which the Irish delegates, Professor Mahaffy, Professor Tyrrell, and Professor Dill spoke with the national fluency and effect, in worthy keeping with the humorous, pathetic, and in all respects admirable speech of the chairman, Principal Donaldson.

One word as to the illustrations, 35 in number, which form an excellent aid to the letterpress, whether in reproducing the portraits of Buchanan at the several stages of his chequered life or in presenting the haunts of his youth, his manhood, his middle age, and his declining years. Portraits taken from photographs of the chief actors in the quatercentenary celebration are also given.

International Clinics. Edited by A. O. J. KELLY, A.M., M.D., Philadelphia, U.S.A. Vols. II. and III., Sixteenth series. 1906. *London and Philadelphia*: J. B. Lippincott Company. Vol. II., pp. 302; Vol. III., pp. 302.

VOLUME II. of the above series contains numerous contributions of considerable interest. Dr. Delancey Rochester (associate professor of the principles and practice of medicine in the University of Buffalo) writes on the Prognosis and Treatment of the Chronic Valvular Diseases of the Heart. He points out that the factors to be taken into consideration in the prognosis of these diseases are: (1) the valve affected; (2) the nature of the lesion; (3) its effect upon the myocardium; and (4) the resultant effect upon the capillary circulation in general and upon the pulmonary and the portal circulation in particular. He also adds that other factors of some value in the prognosis are the causes concerned in the production of the especial valvular lesion under consideration and the associated conditions of the arterial walls. In order to arrive at a correct conclusion as to the prognosis in any particular case all the above points have to be weighed carefully and the two last mentioned are likely to be forgotten, although they are of considerable importance. Dr. Rochester's remarks on treatment are sound and practical. He rightly calls attention to the necessity of lessening the amount of peripheral resistance which the heart has to overcome. If cardiac stimulants only are given without the addition of vaso-dilators harm rather than good may result.

Dr. Philip Jenner (professor of neurology in the Medical College of Ohio) contributes an article on the Prophylaxis of Nervous Disease, with special reference to educational influences in the growing child. He offers some interesting suggestions as to the lines along which a child's education should be conducted. Amongst other contributions to this volume may be mentioned the following: The Diagnosis and Treatment of Abscess and Gangrene of the Lungs, with special reference to Operation, by Dr. Frederick T. Lord, physician to out-patients, Massachusetts General Hospital; Tumours of the Mammary Gland, with special reference to their Diagnosis, Prognosis, and Treatment, by Dr. W. L. Rodman, professor of the principles and practice of surgery in the Medico-Chirurgical College, Philadelphia; and Fœtal Hydrocephalus as a Cause of Delay in Labour, by Dr. J. W. Ballantyne of Edinburgh.

In Volume III. is a paper by Dr. J. W. Patten (professor of diseases of the chest in the Chicago Polyclinic) on the Treatment of Certain Forms of Bronchitis. The author draws attention to infections of the upper bronchial tract due to a variety of micro-organisms, the most important of which are streptococci, staphylococci, and the pathogenic organism of influenza. In the treatment of these forms of bronchitis Dr. Patten points out that there are two important facts to be considered. First, that the expectorants so freely used in the treatment of ordinary forms of bronchitis are practically useless; and secondly, that cough sedatives are inadmissible except in isolated instances. The general principle governing this point is whether the cough is beneficent or not, and if so, whether it is accomplishing its object without causing undue disturbance. Dr. Patten also comments on the value of the iodides in the treatment of bronchitis. He considers iodide of sodium the most generally useful preparation of its class because of "its acceptability to the stomach, because it shows little tendency to cumulative effects, and because it does not cause so much or as lasting depression." Mr. H. S. Clogg (assistant surgeon to Charing Cross Hospital, London) contributes an instructive article on the Diagnosis of some Chronic Joint Affections. His remarks are well worthy of study. He draws attention to the unsatisfactory state of the nomenclature of affections of the joint and adopts the term "osteoarthritis" for a form of disease characterised pathologically by wearing away of the articular cartilage, some atrophy of the bone ends, some osteophytic outgrowths around the margins of the joint, and, in addition, some changes in the ligaments and synovial membrane. The terms "rheumatoid arthritis" and "rheumatic gout" are sometimes applied to this condition but are obviously less accurate. An article by Dr. J. W. Wainwright (New York) on the Predisposition to and the Prevention and Treatment of Pulmonary Tuberculosis, is also well worthy of perusal. Amongst other contributions to this volume attention may be drawn to the following: the Surgical Complications of Pneumonia and their Treatment, by Dr. T. Turner Thomas, assistant surgeon to the University and the Philadelphia General Hospitals; Some Surgical Results which may follow Improper Feeding, by Mr. E. M. Corner, surgeon to out-patients at St. Thomas's Hospital, London; and Leukæmia and Sarcomatosis, by Dr. G. Banti, professor of pathological anatomy in the University of Florence.

LIBRARY TABLE.

Doctors and Patients; and Hospital Heroes. By J. JOHNSTON, M.D. Edin. Annan: W. Cuthbertson.—In these two little pamphlets Dr. Johnston touches on the grave and gay sides of medical practice with equal interest. The heroes include such types as all who work in hospital or general practice must have been the better for meeting, but we feel inclined to cavil at the inclusion of a dramatic account of the voluntary sacrifice of a house surgeon's life by the sucking of diphtheritic mucus from a tracheotomy tube. We respect the author's admiration of a heroic deed that perhaps resulted in the early death of a friend, but we fear that this act has often been a foolhardy and unnecessary one, at any rate in hospitals where appliances should be at hand which could entirely obviate its necessity, and we do not consider that the exploit should be held up as a pattern of duty, although we do not wish to discount the devotion of the many valuable lives that have been sacrificed by a too generous impulse. The "Doctors and Patients" contains some excellent funny stories connected with medical practice. There are certainly some chestnuts in the basket but there are some real plums which are, we think, quite fresh.

The Laws of Health: a Handbook on School Hygiene. By CARSTAIRS C. DOUGLAS, M.D. Edin., D.Sc. (Public Health) Edin., F.R.S.Edin. London and Glasgow: Blackie and Son. Pp. 240. Price 3s. net.—This is a really excellent manual for the purpose for which it was written, which is to give an elementary but sound instruction to teachers in all that concerns the hygiene of children at school. The information has been well chosen and is clearly expressed. Just sufficient anatomy and physiology have been included to enable an ordinarily intelligent reader to appreciate the principles of applied hygiene that depend on them. In a subject which abounds with controversy the author shows no partisanship and deals with the medical inspection and feeding of school children, the use of corporal punishment, and the like, simply from the point of view of the child's health. The ventilation, lighting, and structure of schools are carefully considered and the instruction given on the means of recognising the commoner diseases of childhood and the simple measures of treatment which the teacher may safely carry out himself is quite adequate. Infectious diseases receive the notice that their importance warrants and a useful chapter on physical exercises is included. This book might profitably be read by the medical student as a sound introduction to the study of preventive medicine and will undoubtedly prove of value to teachers in schools.

Medical Examination Questions Set at the University of Edinburgh and Royal Colleges of Physicians and Surgeons of Edinburgh and Faculty of Physicians and Surgeons of Glasgow for Several Years. Edinburgh: John Currie. Pp. 230. Price 2s.—This book contains a good selection of papers set for the various preliminary and final examinations of the above-mentioned bodies. Students who propose to enter within a short time for any of these or other medical examinations will find it of value in their preparation as it covers a wide range of questions. The use of some such test is to be recommended, as not a few students undoubtedly fail chiefly through their inability to impart their knowledge to their examiners in an intelligible manner. The value of the present book would be improved if the time allowed for the various papers were mentioned. We understand that it will be produced annually in May.

The City of London Directory, 1907. London: W. H. and L. Collingridge. Pp. 1178. Price 12s. 6d.—This Directory, of which the present is the thirty-seventh annual edition, contains much valuable information not easily otherwise accessible concerning the City of London, the corporation, the livery companies, and other public bodies responsible for the government of Greater London. The Biographical Section, comprising portraits and biographies of the aldermen and principal officers of the corporation, the City Members of Parliament, and many of the masters of the livery companies, is both useful and engaging. The section devoted to the livery companies is full of historical facts and quaint records of charity which conjure up to the mind's eye scenes in the life of old London. The Directory also contains the usual alphabetical list of names, the list of streets and houses with their occupiers, and the list of trades and their followers. A large coloured map, which shows admirably the details o "the one square mile," is a most useful adjunct to the work

JOURNALS AND MAGAZINES.

The Quarterly Journal of Microscopical Science. Edited by E. RAY LANKESTER, M A., F.R S., with the coöperation of ADAM SEDGWICK, F.R.S., SYDNEY J. HICKSON, F.R.S., and E. A. MINCHIN, M.A. With Lithographic Plates and Text Figures. London: J. and A. Churchill. New Series. No. 202. Pp. 177. Price 10*s.*—The contents of this part are: 1. The Origin and Nature of the Green Cells of Convoluta Roscoffensis, by Frederick Keeble, M.A., D.Sc., and F. W. Gamble, D.Sc. This article, which is illustrated by two well-executed plates, affords evidences of entry of the green cells of an alga into the colourless body of convoluta roscoffensis after hatching. Infection takes place from the sea water or from chemotactic attraction between the infecting organism and the egg capsules. The green cells are incapable of living when isolated from the animal. The infecting organism shows the essential characters of the chlamydomonidæ; the green cells serve as an excretory system to the animal. Finally, the relation between the green cells and the animal changes, passing from a symbiotic relation to one in which the animal is parasitic on the algal cells. The association leads to alteration of habit on the part of the animal—as, for example, its ceasing to ingest food—and is best interpreted as an economically unsound attempt on the part of both green cell and animal to solve the "nitrogen problem." 2. On the Development of Plumes in Buds of Cephalodiscus, by W. G. Ridewood, D.Sc. Dr. Ridewood reproduces the figures and statements in regard to the plumes of cephalodiscus dodecalophus published in the Transactions of the Royal Society of Edinburgh for 1898 and contests their accuracy not only in the case of cephalodiscus dodecalophus but in C. Hodgsoni, C. nigrescens, and C. Gilchristi. In particular he finds that the torsion of the axes of the first and second plumes of the buds of cephalodiscus described by Masterman does not occur. He considers that the last two pairs of plumes arise on the dorsal side of the first two pairs of plumes and the buccal shield and not between the first two pairs of plumes and the buccal shield as described by Masterman. He finds, too, that the plume axes develop in pairs successively and when the third and fourth pair of plume axes (there are seven in all) are beginning to develop the edge of the post-oral lamella is in contact with it and with each last developed pair of plume axes. The line of plume bases in the adult when viewed from the front is an ellipse incomplete on the upper side, and the line of the attached edge of the post-oral lamella forms another ellipse similarly incomplete. The two ellipses join where they are incomplete. 3. On the Structure of Ænigma Ænigmatica, Chemnitz: a contribution to our Knowledge of the Lamellibranchiate Anomiacæ, with three plates, by Gilbert C. Bourne, D.Sc Oxon. The Ænigma is one of the genera of the oyster family found living on the roots and branches of Nipa, a palm growing at Sarawak. It is allied to the Anomia ephippium and is capable of resisting desiccation for long periods of time. Dr. Bourne gives a very careful description of the specimens which he examined with illustrations of the anatomy: 4. On the Chromatin Masses of Piroplasma Bigeminum (Babesia Bovis), the Parasite of Texas Cattle Fever or Red Water Fever, by H. B. Fantham, B.Sc. Lond., with a plate and 44 figures in the text. The chromatin masses were found in pairs in the interior of the blood corpuscles and were of pyriform shape. About 90 per cent. of the blood corpuscles were infected. 5. The Skin, Hair, and Reproductive Organs of Notoryctes typhlops (Stirling) Parts IV. and V., by Georgina Sweet, D.Sc., Melbourne University. This animal belongs to the marsupial group and the parts mentioned are fully described and compared with similar parts in other genera of marsupials. 6. Parorchis acanthus: the Type of a New Genus of Trematodes, by William Nicoll, M.A., B.Sc., with a plate. Two specimens were found in the bursa Fabricii of the herring gull (*Larus argentatus*), and others in the same position in Larus canus. The usual length of the animal is from three to five millimetres. The suckers are globular and highly muscular; the oral sucker is the larger of the two. The alimentary system is well developed. The excretory system presents several peculiarities: it has two wide median and two lateral trunks which communicate posteriorly with a vesicle which is of irregular form, situated at the hind end of the body, and presents on each side about four short unsymmetrical branches. It has a dorsal aperture.

The Bio-Chemical Journal. Edited by BENJAMIN MOORE, D.Sc., and EDWARD WHITLEY, M.A. Vol. II., Nos. 5 and 6. May 22nd, 1907. Published by the Bio-Chemical Department, Johnston Laboratories, University of Liverpool. Pp. 107 Annual subscription, 15*s.*—The articles contained in these numbers are: 1. A New Case of Alkaptonuria, by Archibald E. Garrod and J. Wood Clarke. The patient was a girl three years of age, an only child, and there was no blood relationship between the parents. The nurse noticed that her apron was stained on the second day of the child's life; appropriate tests showed that the dark colour was due to the presence of homogentisic acid. There was no second alkapton acid. The quantity of the acid daily excreted was 1·832 grammes. The amount excreted represented all the tyrosin and phenylalanin of the proteins broken down. 2. On the Size of the Cells of Pleurococcus and Saccharomyces in Solutions of a Neutral Salt, by Eric Drabble, D.Sc., Hilda Drabble, and Daisy Scott, M.Sc. The authors show that the cells of yeast and pleurococcus undergo decrease in size with increase in the external osmotic pressure of the medium in which they lie. Hence plasmolysis fails as a ready means of determining the *osmotic strength* of their cell sap, but in mature cells of multicellular plants the plasmolytic method is capable of yielding trustworthy and approximately correct measurements of the osmotic strength of the cell sap, for in them the extensibility of the cell wall is generally negligible and increase in osmotic strength of the osmotic medium fails to cause shrinkage of the cell until the externally and internally directed pressures are equal. From that stage onwards increase in concentration of the external medium results in plasmolysis. 3. Metabolism in a Vegetarian, by William Gordon Little, M.D. Edin., and Charles E. Harris, Ph.D. Erlangen. 4. Ergotoxin and some other Constituents of Ergot, by G. Barger, M.A. Cantab., and H. H. Dale, M.A. Cantab.; this is a long and valuable article. 5. On the Treatment of Trypanosomiasis by Atoxyl (an Organic Arsenical Compound) followed by a Mercuric Salt (Mercuric Chloride), being a bio-chemical study of the reaction of a parasitic protozoon to different chemical reagents at different stages of its life-history, by Benjamin Moore, D.Sc., Maximilien Nierenstein, Ph.D. Berne, and John L. Todd, B.A., M.D. McGill.

Reports and Analytical Records

FROM

THE LANCET LABORATORY.

(1) FERRO-MANGAN PREPARATIONS; AND (2) REGULIN.

(MATTHAEI AND CO, AGENTS, 12 AND 15, CULLUM-STREET, LONDON, E C.)

1. WE have carefully examined the ferro-mangan preparations, with the result that we found that their composition is correctly detailed. Dieterich's ferro-mangan is a non-alcoholic fluid in which both iron and manganese occur in the form of organic compounds—namely, peptonates. This

preparation has been reported on very favourably in German clinics in cases of anæmia, the results showing generally a manifest improvement in the hæmoglobin content of the blood. An important feature of the preparation is that whilst it exhibits a good proportion of iron the metal is not presented in the form of ordinary salts which disturb digestion. The usefulness of the compound is extended by combining it with bromine and iodine respectively. The first is stated to be employed with favourable results in conditions of poorness of blood associated with nervous disorders; and the second in similar conditions co-existent with diseases of the glandular system and in rheumatic affections. Our experiments confirmed the statement in regard to the individual constituents set forth. 2. Regulin is an interesting preparation which has been employed according to German clinics in the rational treatment of chronic habitual constipation. Regulin is a preparation of agar-agar in the form of flakes. It is said effectually to soften the fæces which are then readily evacuated. Agar-agar passes through the digestive tract unchanged except that it swells in the mouth and still more in the stomach. The action of agar-agar is, of course, materially helped by the presence of the extract of cascara sagrada. Regulin, in short, is cascara agar.

(1) ERNUTIN; (2) CHLOROFORM; AND (3) ETHER.

(MESSRS. BURROUGHS, WELLCOME, AND CO., SNOW-HILL BUILDINGS, LONDON, E.C.)

1. Ernutin represents the active principles of ergot in a condition of chemical purity. It is stated to be physiologically standardised by observing its effect on the vaso-motor functions of the sympathetic nervous system. Ergotoxin has been obtained as a pure crystalline salt in the Wellcome Physiological Research Laboratories. The isolation of a definitely pure salt from ergot has filled a decided gap in therapeutics—namely, the standardisation of ergot principles. Under the name ernutin ergotoxin is supplied in tabloid form and also in hermetically sealed phials for hypodermic use. 2. The specimen of chloroform was contained in an amber-coloured glass tube which preserves the purity of the chloroform, keeping it in particular away from the decomposing action of air and daylight. 3. The specimen of ether was contained in a hermetically sealed glass tube and on examination proved to satisfy the requirements of the British Pharmacopœia for pure ether. The tubes are packed in a wooden container and the contents measure 30 cubic centimetres or 60 cubic centimetres, in accordance with the quantity which is found convenient for use.

CALYX PHOSPHATIC CORN-FLOUR.

(THE CALYX MANUFACTURING COMPANY, 16, WATER-LANE, GREAT TOWER STREET, LONDON, E.C.)

The title of this preparation sufficiently describes it. We found it to consist of ordinary corn-flour—that is, maize-flour—to which phosphates, chiefly of calcium, have been added. Ordinary corn-flour yields an ash equivalent to 0·51 per cent. Calyx corn-flour yields 2·20 per cent. of ash, the difference representing the amount of phosphate added. The suggestion of adding phosphates to food is, of course, not new. Such a food would be useful when a deficiency of phosphates exists.

OATMEAL STOUT.

(BARCLAY, PERKINS, AND CO., LIMITED, LONDON, S.E.)

The effect of brewing stout with the addition of oatmeal is calculated to increase the nourishing quality of the malt liquor, inasmuch as oatmeal contains more protein than does barley. This is borne out by our analysis of this stout, the extractives of which contain 8·20 per cent. of protein. Further results were as follows: alcohol by weight 4·62 per cent., by volume 5·78 per cent.; extractives, 5·67 per cent.; and mineral matter, 0·27 per cent. We have examined stouts containing a higher proportion of extractives than is shown above but the proportion of proteins in these extractives is satisfactory. The stout was in good sound condition and possessed a pleasant bitter flavour due to hops.

(1) WHITE VOSLAUER GOLDECK; AND (2) SPARKLING GOLDECK.

(H. SCHLUTER AND CO., 50, MARK-LANE, LONDON, E.C.)

We have already referred in these columns to the excellent red wines known as Voslauer and produced in Austria. 1. We have recently received specimens of a still white Voslauer wine which, it is stated, is allowed in the regimen of the patients undergoing the Schroth-Cantani treatment. However this may be, we found the wine to be of comparatively low alcoholic strength, "dry," and free from acidity. The flavour is delicate. Our analysis gave the following results: alcohol, by weight 7·93 per cent., by volume 9·86 per cent.; extractives, 1·90 per cent.; sugar, 1·0 per cent.; mineral matter, 0·22 per cent.; volatile acidity reckoned as acetic acid, 0·18 per cent.; and fixed acidity reckoned as tartaric acid, 0·54 per cent. It is obviously a wine of fine delicate quality. 2. Sparkling Goldeck presents all the qualities of a good champagne and the results of its analysis show no important differences. They were as follows: alcohol, by weight 10·46 per cent., by volume 12·98 per cent.; extractives, 3·40 per cent.; mineral matter, 0·07 per cent.; volatile acidity reckoned as acetic acid, 0·168 per cent.; fixed acidity reckoned as tartaric acid, 0·54 per cent.; and sugar, 2·46 per cent. The wine has a pleasing flavour and is correctly described as dry, inasmuch as it contains no more sugar than is present in good champagne.

(1) FORMIDINE; (2) SALINE LAXATIVE (EFFERVESCENT); (3) CATHARTIC COMPOUND; AND (4) TRIPLE GLYCERO-PHOSPHATES WITH NUCLEIN.

(PARKE, DAVIS, AND CO., 111, QUEEN VICTORIA-STREET, LONDON, E.C.)

1. Formidine is the name given to a powerful antiseptic adapted for either internal or external use, and chemically it is methylene di-salicylic acid iodide. We had no difficulty in finding salicylic acid and iodide present. It is further described as a condensation product of iodine, formic aldehyde, and salicylic acid; the *rationale* of its antiseptic action will therefore be understood. It appears to be useful for checking bacterial infections of the intestinal tract, whilst it is employed also as a dusting powder for various skin affections. It is said to be without toxic effects. 2. The saline laxative is a well-prepared granular effervescent mixture of the laxative salts, sodium sulphate, sodium phosphate, and magnesium sulphate. It effervesces agreeably and keeps well. 3. The cathartic compound is contained in chocolate-coated tablets, each tablet containing one grain of compound extract of colichon, half a grain of extract of jalap, half a grain of extract of gentian, a quarter of a grain of podophyllum resin, a quarter of a grain of leptandrin, a quarter of a grain of extract of hyoscyamus, and a sufficiency of oil of peppermint. This mass is said to operate without pain or flatulence. 4. The addition of nuclein to the triple glycerophosphates is an advantage, inasmuch as it exhibits a bactericidal action and also has the power of increasing leucocytosis. The combination is suggested as being useful in debilitated conditions generally.

NON-ALCOHOLIC BEER.

(AGENCY: H. D. WELLS AND CO., PRINCES DOCK SIDE, HULL.)

This beer is brewed in Norway and is practically non-alcoholic, the alcohol, according to our analysis, not exceeding 1·0 per cent. by weight. The beer is slightly effervescent and possesses a pleasant and somewhat rich malty flavour. It contains at least 10·0 per cent. of malt extractives and the mineral matter amounting to 0·20 per cent. abounds in soluble phosphates. The malt sugar amounted to 6·42 per cent. In short, this beer is in reality a malt extract. The flavour is decidedly good and the beverage proves to be refreshing and, of course, at the same time it presents a distinct amount of nourishing material.

THE LANCET.

LONDON: SATURDAY, JUNE 29, 1907.

Royal College of Surgeons of England.

THE constitution of the Royal College of Surgeons of England wisely ordains that there shall be at least three vacancies on the Council each year to be filled at the annual meeting of Fellows in July. At the election this year there will be four vacancies, because Sir John Tweedy's term of office was extended owing to the fact that he was President when the period for which he was elected came to an end. We understand that he has decided not to offer himself for re-election, and while we approve of the principle that repeated re-elections are undesirable we cannot but feel that this determination on the part of Sir John Tweedy will mean a very real loss to the College. He discharged the duties attaching to the arduous post of President for three years with satisfaction to the College and with the approbation of all those whose knowledge of College affairs qualifies them to judge. Though Sir John Tweedy has held, and still holds, advanced views on College politics, yet he succeeded in working most amicably with his colleagues, including those whose views differed widely from his own.

The three other retiring members of the Council are Mr. Herbert W. Page, Mr. C. W. Mansell Moullin, and Mr. Frederick S. Eve, and they have all decided to apply for reappointment. There is no rule or custom against retiring candidates reapplying, and indeed at each election one or two do so, but we do not remember any occasion on which all the three members who retire in rotation have decided to offer themselves once more. When a member of the Council has done good work on that body and has during his term of office grown thoroughly familiar with all the methods in which the business of the Council is carried on there is a very good reason for his continuance on the Council for another term, but at each election fresh blood should be introduced in order to prevent the Council becoming out of date. Therefore, without wishing to cast any aspersion on the three retiring members who seek re-election, we think that it is undesirable that all three should be re-elected. In this connexion we must consider, too, the candidates who have not hitherto been members of the Council. These are four in number and we mention them in order of seniority—Mr. Charles Higgens, Mr. W. Bruce Clarke, Mr. Charters J. Symonds, and Mr. W. Dunnett Spanton. Mr. Charles Higgens is now consulting ophthalmic surgeon to Guy's Hospital. He obtained his Fellowship in 1871 and he has done much work in ophthalmology. The retirement of Sir John Tweedy from the Council leaves only one ophthalmic surgeon there—namely, Mr. F. Richardson Cross—and that may be an argument in favour of Mr. Higgens's claims. We are not aware that he has hitherto shown any special interest in College affairs, but his ripe experience would doubtlessly prove of much service on the Council. Mr. W. Bruce Clarke has been a Fellow since 1877. He is surgeon to St. Bartholomew's Hospital and has for many years taken an active part in College politics. He has been a candidate on three previous occasions, first in 1904, and again in 1905, when he retired before the date of election in order not to prejudice the chances of his colleague, Mr. Harrison Cripps, but as this was after the voting forms were printed it was too late to prevent his name appearing before the electors. In 1906 he was also a candidate and he received only 35 votes less than the number recorded for the lowest successful candidate. Mr. Charters Symonds obtained his Fellowship in 1881. He is surgeon to Guy's Hospital and lecturer on surgery to the medical school. He also was an unsuccessful candidate at the election last year and he obtained only 24 votes less than sufficed to elect Mr. Richardson Cross. Mr. Symonds would be a valuable member of the Council. Mr. Spanton of Hanley was elected a Fellow in 1898 under the clause by which Members of 20 years' standing may be elected as Fellows. He is consulting surgeon to the North Staffordshire Infirmary and he has done much good work in surgery.

In coming to a decision as to the most suitable candidates to support at the coming election we have to consider, not merely the relative merits of the candidates but also the medical schools which they represent. Further, we have to bear in mind that, as a rule, provincial Fellows find it difficult to attend regularly at the meetings of the committees which transact so great a portion of the work of the Council. At present there are five provincial members on the Council and we can see no reason for increasing this number. This in itself appears to us to be an argument against Mr. Spanton's claims which somewhat overbalances certain other circumstances in his candidature which suggest that his election would make for the liberalising of the constitution of the College. Of the three retiring members of the Council two belong to the London Hospital. This is certainly no more than the importance of that medical school deserves, but having regard to the desirability of the infusion of fresh blood we think that it is advisable to reappoint only one of these representatives of the London Hospital. With regard to Mr. Bruce Clarke it may be said that St. Bartholomew's Hospital is already fully represented on the Council, but it must not be forgotten that nearly a quarter of the whole list of Fellows comes from that hospital, and therefore perhaps it may not be considered unreasonable that it should have more than its strict proportion of representatives. As we have already mentioned Mr. Bruce Clarke has for some years taken a keen interest in matters concerning the College and we think that his election would add strength to the Council. Therefore, for the four vacancies which have to be filled on Thursday, July 4th, we consider that the most suitable candidates are Mr. H. W. Page, Mr. W. Bruce Clarke, Mr. Charters J. Symonds, and one of the representatives of the London Hospital. To vote under the present conditions is a very simple matter. Voting papers are sent without any request to all Fellows resident in the British Isles and the directions for filling up the voting papers are perfectly clear. Yet it is found that several papers are incorrectly filled up, that more votes are given than there are places vacant, and that several papers usually arrive too late for the election. The signature of each voter has to be attested by a witness; but on a recent occasion one Fellow witnessed his own signature. The vote was, of course, disallowed. With all the facilities for voting it is hard to believe that only about half the Fellows take the trouble to vote. The number of Fellows who vote in person is yearly diminishing and it is becoming increasingly difficult to muster the six Fellows unconnected with the Council who must be present before the election can commence. The time has been postponed to 3 o'clock to make it easier for Fellows to attend, and we hope that many will be present on July 4th at that hour at the College to facilitate the counting of the votes.

◆

Inflammation.

IT is a well-known principle that as knowledge advances concepts which at first were clear and sharply defined tend to enlarge their boundaries and in the process to lose in definiteness what they gain in extension. An example from the realm of metaphysics may be found in the development of the idea of causation. In the twilight of knowledge man saw everything in an anthropomorphic light and assigned all natural phenomena to the action of living beings more powerful perhaps than himself but acting on similar motives and in similar ways. The cause of any phenomenon was the will of some god or demon: the lightning was hurled by ZEUS; the rain fell by his command; the sun was driven across the sky by APOLLO; and storms were stirred up by POSEIDON. With further observation came the knowledge of uniform sequences among natural phenomena and the cause of any one of them was looked for in those which immediately preceded it. A cause was an invariable antecedent. Still later the idea of evolution arose and it was realised that the universe exhibited an endless procession of events and that the cause of any one was really the whole history of the world, traceable through an unending chain of causes and effects, each new pattern in the kaleidoscope being merely a rearrangement of pieces that had existed for all time. The idea of causation thus expanded into the larger conception of endless ordered change.

A similar expansion is to be seen in the history of the idea of inflammation. At first the concept was simple and clean-cut. The phenomena of redness, swelling, heat, and pain, as seen in certain conditions of the living body, formed a definite group, easily separable from other diseases, such as wounds, fevers, tumours, or apoplexies. A cut or stab might heal up without trouble and be well in a few days, or it might become inflamed, pour out pus, and take weeks before it was well. Nothing could seem clearer than the difference between such conditions. But with the advent of the microscope it became possible to identify the actual series of changes which occurred in an inflamed wound; the redness was found to be caused by dilatation of vessels, the swelling by escape of fluid into the tissues, the pain to be due to tension thus produced and to resulting pressure on nerve terminals, and the heat to increased flow of blood through the part. Cells were destroyed in the process, leucocytes escaped into the tissues, and the lesion was at last repaired by a growth of new fibrous tissue forming a scar. Still the conception of inflammation remained clear and its nature was to some extent explained. But increase of knowledge showed that practically the same phenomena of vascular dilatation, escape of serum and leucocytes, and final repair by fibrous tissue are met with in a simple wound which heals by first intention; some of them follow in a bloodless part such as the cornea when cells are destroyed. The concept, inflammation, now had to be widened so as to include conditions to which the name had never been meant to apply—conditions, indeed, with which it had originally been sharply contrasted. At this stage the well-known definition coined by BURDON-SANDERSON was generally accepted, inflammation being regarded as the reaction of living tissues to an irritant which was not intense enough to cause their immediate death. But criticism and inquiry continued. It was pointed out that if inflammation were a pathological process the repair which follows it cannot be part of the concept, yet it is impossible to separate the destructive from the reparative phenomena. Indeed, in view of the bacterial causation of most examples of inflammation and of the tendency of the exudation to antagonise the invading organisms the whole of the process might be looked upon as defensive and repair merely as the final stage of it. Further, it is impossible to draw any logical distinction between the local phenomena of cellular destruction by toxic agents and the remote consequences of the absorption of these substances seen in fever and parenchymatous degeneration of distant organs; these must also be included. This logical extension is recognised by RIBBERT in his teaching on the subject of inflammation. Some observers further believe that the formation of tumours is due to chronic irritation by agents of low virulence, so that this branch of pathology would also be properly brought under the heading of inflammatory reaction. Thus with increase of knowledge the borders of the realm of inflammation have become so far extended that it embraces almost all the province of pathology and becomes coextensive almost with the idea of disease itself. It is clear that in the process of extension the term has lost its value, and if it is to be retained at all it must be artificially restricted to some portion only of its pathological contents.

Professor J. G. ADAMI, in the admirable article which he contributed to the new edition of Professor T. CLIFFORD ALLBUTT'S and Dr. H. D. ROLLESTON'S "System of Medicine," and which has now been reprinted as a separate volume[1]—an article which serves as the text and basis of these reflections—refuses to accept the final extension admitted by RIBBERT and restricts the term inflammation to local phenomena; yet even then the concept is too wide for general use. It is true that the origin of tumours in continued slight irritation accepted by Professor ADAMI is not by any means established and that this group of maladies must for the present remain contrasted with inflammatory conditions, but to depart so far from the original idea of inflammation and from the popular use of the term as to include the healing of a simple aseptic incision seems undesirable, if we are once to sanction a departure from strict logical and pathological canons. It is rather desirable to return so far as possible to the ancient point of view—to the redness, swelling, pain, and heat of CELSUS—and to endeavour to find the peculiarities which differentiate this group of symptoms from other allied phenomena. Now it is clear that without the presence of vessels there can be no redness or heat, and that their part in the production of swelling is also considerable. Therefore, there would seem justification for restricting the term inflammation to the reaction of vascular parts to injury. But the healing of a wound in a vascular part by first intention is clearly not inflammatory in the popular sense and should be excluded if any distinction can be found between the two processes. Since in most cases inflammation is induced by the entrance of pathogenic bacteria it has been suggested to limit the use of the word inflammation to conditions produced by these agents; but this appears undesirable since simple chemical substances, such as croton oil, are quite capable of exciting a condition exactly resembling that due to micro organisms. Some other criterion must be sought. Now the difference between a simple and an inflamed wound lies in the fact that the former is due to the momentary action of an irritant, the latter to the continued action of the poisonous substances introduced into the tissues. Hence the idea of chronicity seems to form part of the connotation of inflammation which might be roughly defined as the reaction of a living vascular tissue to continued irritation. So restricted the term would include all those conditions which are usually classified as inflammatory and the process of healing which ensues. On rigid pathological grounds the restriction, it is true, cannot be logically justified (nor can an exact definition of what constitutes chronicity be given), but it would enable a popular and essentially clinical term to be retained without undue stretching of its meaning and without the introduction of any teleological conceptions to which some writers have raised objection.

---

[1] Inflammation: An Introduction to the Study of Pathology, by J. George Adami, M.A., M.D., F.R.S., Professor of Pathology, McGill University, Montreal. London: Macmillan and Co., 1907, price 5s. net.

The Tenure of the Appointments of Medical Officers of Health.

FOR many years past, indeed almost from the date of the passing of the Public Health Act, 1875, the appointment of medical officers of health for short periods of one or more years has militated against proper and satisfactory sanitary administration, more especially in the small urban and rural districts. The subject has been referred to not only by medical officers of health themselves, who may be looked upon by some as not altogether disinterested parties, but by the medical inspectors of the Local Government Board and by Parliamentary and departmental committees whose inquiries have not been directly connected with the question. The Inter-departmental Committee on Physical Deterioration in 1904 stated most definitely that "a medical officer of health in all areas above a certain population should be required to give his whole time to the work, and in no case, unless convicted of misconduct, should a medical officer of health so engaged be removed without the consent of the Local Government Board." At the end of last year Sir JOHN DICKSON-POYNDER'S Select Committee on the Housing of the Working Classes Acts Amendment Bill recommended that medical officers of health should "hold their appointments during good behaviour and be removable only with the consent of the Local Government Board." A recommendation in almost identical terms was made more than 20 years ago by the Royal Commission on Housing and by the Royal Commission on Labour. Recommendations such as these, coming as they do from those who are above all suspicion of partiality or an obsequious respect for officialism, have up to the present been almost entirely ignored. Beyond an occasional suggestion to a sanitary authority, which asked permission to reappoint a medical officer of health for a further 12 months, that the "Board would raise no objection to his appointment without reference to time," the Local Government Board has made no effort to give effect to the recommendations which we have quoted. We have no desire to be otherwise than quite fair to the Board, the difficulties of which are admittedly great, and although no public pronouncement has been made either by the present President or by any of his predecessors, nor indeed by any of the permanent officials of the Board, it is generally believed that it has long been the intention of the Board to introduce legislation which should have the effect of increasing the number of combined sanitary areas having whole-time medical officers of health and of gradually abolishing the single districts with badly paid officers who are engaged in private practice. If we are correct in this conjecture it is not at all difficult to understand that the Board would be lacking in prudence by consenting actively to support any proposal which would not harmonise with subsequent schemes.

We do not pretend to be in the confidence of Mr. JOHN BURNS but we believe it is not at all unlikely that the Housing Bill, the draft of which the Prime Minister has stated can be laid before the House of Commons at any moment, contains clauses to give practical effect to the intentions of the Board to the extent which we have indicated. There appears, unfortunately, to be very little possibility of the Housing Bill coming before Parliament during this session and this being so we would suggest that the President of the Local Government Board might very well consider the practicability of making the appointments non-lapsing of those medical officers of health who are at present engaged in large combined districts, who are specially qualified for their work, and who devote the whole of their time to their duties. By doing so he would, at any rate, show that he was honestly desirous of giving effect to the recommendations to which we have already referred. The particular manner in which this suggestion should be carried out must necessarily be left to Mr. BURNS and his advisers at the Local Government Board. The Board has powers, we believe, to make an Order which would have the effect of making the appointments non-lapsing of those medical officers of health whose salaries are partly paid out of county council funds. For reasons already stated the Local Government Board may not be desirous of extending this principle to all appointments, but it ought not to be a very difficult matter so to frame an Order that it would not be out of harmony with future legislation contemplated by the Board.

Legislation introduced by the present Government in the interests of the public health has been meagre in the extreme but there is an opportunity now of carrying out a reform which will have the most far-reaching results. Those results will not be confined to the 2,000,000 persons who live within the existing combined sanitary areas; they will be felt in the small towns and in the county boroughs. They will include a cleaner and a purer milk-supply, a more vigilant inspection of slaughtered cattle, increased supervision of fruit and vegetable pickers, and the carrying out of such measures as will give to those who live in urban districts a far greater sense of security regarding their food-supplies than they can possibly have at the present time. We cannot believe that the Government, supported as it is by so large a number of labour representatives, will neglect this chance of carrying out with little or no effort a reform which will result in so large a measure of benefit to the working classes.

Annotations.

"Ne quid nimis."

THE WORKMEN'S COMPENSATION ACT.

SINCE the enactment of the Workmen's Compensation Act that will come into operation next week we have frequently commented on those of its issues which more especially affect the medical man. As recently as May 11th we described in our editorial columns the agency established by the Medical Insurance Committee—a committee of medical men formed at the instance of THE LANCET and the *British Medical Journal*—through which members of our profession will be able to insure against all liabilities, including those arising under the Act, at very favourable terms under the policies of the Guardian Insurance Company, Limited. We think it advisable again to direct attention at this eleventh hour to the great importance of medical men making some such provision, and we take the opportunity to discuss more fully one or two points that we have already raised. The question as to whether a locum-tenent can benefit under the Act is a point of outstanding importance. Although it is true that a salary of 4 guineas a week with board or other allowances is equal to more than the £250 a year that will exclude him from the benefits of the Act, yet it must be remembered that he is not continuously employed for the whole year and so it may well be contended that he is entitled to them. Trained nurses, dispensers, and errand boys also come under its provisions, as although they may be only "occasionally employed," yet their services are required "for the purposes of the employer's trade or business." It is not clear whether charwomen or other such "casual" servants who meet with accidents in medical men's surgeries will have an equal claim; but in this, as well as in any other case where the nature of employment in its relation to the Act admits of much doubt the wiser course will be to insure, at any rate, until the extensive litigation that is certain to ensue has decided a similar case in the employer's favour. One further point that deserves notice is the responsibility for an accident to the coachman of a carriage jobbed by a medical man. The safest course for the latter to pursue is to obtain a written undertaking from the jobmaster that he will bear the responsibility for any claim arising from an accident to the coachman who is, of course, primarily his servant. We may conclude these remarks by again calling attention to the advertisement of the Guardian Company which has undertaken to carry out the scheme of the Medical Insurance Committee. The premiums are moderate and the policy offered not only indemnifies the insurer against the complete liability under the Act but also covers the cost of litigation where wrongful claims for accidents are made and so offers a much-needed protection against the "speculative action" brought by a man of straw against his employer at another's instigation.

TEMPERANCE AND THE "WINE WAR" IN THE SOUTH OF FRANCE.

To the advocates of real temperance the disturbances in the South of France should serve as a useful object-lesson. Here is a country where the over-production of wine has created great distress. Wine is now so cheap that the wine-growers are starving, but this wine, which costs less than the barrel or the bottle in which it is placed, does not produce drunkenness. The physical and moral degeneration which on the continent differentiates the term alcoholism from drunkenness is almost unknown in that part of France. So obvious is it that wine-growing countries are free from the curse of alcoholism that natural light wines are qualified as hygienic drinks and, as fully explained in these columns, all taxes have been removed so as to enable the people freely to drink pure wine.[1] When studying this temperance legislation our Special Commissioner photographed a grocer's shop at the corner of the rue Monge, Paris. Here were barrels containing wine from the very department where the town of Narbonne is situated and the greatest disturbances have occurred. This wine from the department of the Aude was advertised at the retail price of 20 centimes, or 2*d*., per litre, or about 1¼*d*. per the English pint. Our Commissioner bought a litre; it was tasted and analysed in THE LANCET laboratory. The wine was quite palatable and, chemically speaking, was the same as high-class and expensive clarets. Of course, it was wine fresh from the wood. Clarets are only expensive when they come from some well-known vineyards, possess a peculiar *bouquet*, and have been bottled and stored for a considerable time. Otherwise the excellent clarets now retailed in Paris for from 2*d*. to 4*d*. per litre should be sold in London, after paying an entrance duty of 3½*d*. per litre, at from 6*d*. to 10*d*. per litre, or from 4*d*. to 6*d*. per pint. This, however, is only the case in the French quarter of London where there are a quick consumption of wine and a population that knows something about natural and wholesome wines. The difficulty in England is that the public will not drink wine because it cannot realise that wine should be, *and is*, in spite of duty, as cheap as bottled ale and stout. At the same time, it is less "heady," mixes admirably with water, and especially in summer provides a long, refreshing, and innocent drink. The disturbances in the South of France should make the British public realise how cheap is the natural, freshly made, new wine—the wine which is poured out into a tumbler that has generally an ornamental design in the lower portion of the glass reaching a third of the way up. It is bad manners, a sign of coarse breeding, to pour wine above this mark or to fill more than a third of a big glass. The water pitcher follows the litre bottle and at least 50 per cent. of water is added to wine that rarely contains more than 10 per cent., and never more than 12 per cent., of alcohol. This is the national drink of the sober French people. Not only men but women and children for hundreds of years have drunk these simple, cheap wines and the idea that any harm could result therefrom has never dawned upon them till foreign ingredients were added to the wine. An added alcohol, especially if not made from grape, might prove highly mischievous. Whatever the trade and the large owners of vintages may have done, the mass of the people realised that their prosperity depended on the purity of their produce. In 1904 a congress of agricultural labourers was held at Narbonne and they then asked that the law should protect them against employers who falsified the wine. The other day, in the French Chamber, the Deputy, M. Vaillant, who is a Member of the Royal College of Surgeons of England, moved a clause to the effect that if a labourer was dismissed because he refused to practise fraud in the making of wine his employer should be condemned to pay him an indemnity. The obvious moral of the present disturbance is the necessity of taking measures to insure that only pure wine shall be placed on the market. This will best serve the interests of honest growers in the wine countries and the cause of temperance throughout the world.

THE AIR OF THE STOCK EXCHANGE.

IN busy times there can be no doubt at all that the air of the Stock Exchange is not fit for healthy men to breathe. We do not propose to penetrate into the recesses of "the House" to prove our words. That privilege might conceivably be denied us, but at least we are in possession of facts gained in quite another way which are of greater weight than chemical experiments relating to the impurities of the air, or even than bacteriological experiments recording the number and species of bacteria in the atmosphere of "the House" during or after a hard day's proceedings. Clinical experience is convincing in this matter and its teachings are that the air of the Stock Exchange must be both chemically and bacteriologically bad. If it were otherwise it would be difficult to account for the complaints of malaise, headache, depression, and a feeling of being "run down" which have reached us through medical practitioners who have amongst their patients men whose business it is to transact Stock Exchange dealings. Bustle is a necessary feature of this work and we learn through newspaper channels that frequently excitement runs high, that feelings are manifested in physical methods of expressing emphasis, and that there are much running about, shouting, shuffling of feet, and beating of tables, all of which form agencies favouring the distribution of disease-bearing materials. If there is a place which demands the very best that the science of sanitation and ventilation can afford surely it is the Stock Exchange. Yet we feel certain that the arrangements made in this great centre of financial transactions fall lamentably short of a sanitary standard and accordingly it must claim its victims to those diseases which are a corollary of inspiring air polluted with foul gases, human exhalations, and infected dust. The fatigued man is a poisoned creature, hence his fatigue, and only rest and good food and air can extricate him from his position. Fatigue is, of course, the normal sequel of hard work, but it may be abnormally rapid in following work which is done in an unhealthy environment. In that case fatigue becomes severe and is accompanied by marked symptoms of ill-health apart altogether from the question of the evils which arise from the invasion of pathogenic organisms. We counsel the members of the Stock Exchange to remind its managers of the necessity of setting "the House" in order from a sanitary point of view, so that, considering the special circumstances of the case, every step may be taken to secure a place of business for them which conforms to high hygienic requirements and which is not open to the reproach of lowering the standard of health of those who are bound to put in an attendance there.

AN APPEAL FOR UNIVERSITY COLLEGE HOSPITAL.

UNIVERSITY College Hospital has recently issued an appeal for more support based on the overwhelming argument that since the beginning of last year the committee has been forced to sell over £12,000 of stock to meet pressing tradesmen's bills. That there has been a strict economy exercised is proved by the fact that the average cost of occupied beds was reduced from £99 14*s.* 8¼*d.* in 1905 to £87 0*s.* 7¾*d.* in 1906. The committee especially appeals for further permanent endowment of beds and cots. It is to be hoped that so necessary an institution will not be forced to close any beds for lack of funds. The melancholy spectacle of idle wards, closed for lack of funds, may be seen in more than one London hospital which has perforce daily to refuse admission to cases for lack of accommodation, and we heartily recommend the latest appellant to the charitable to save it from the risk of a like sad necessity.

THE SANATORIUM TREATMENT OF PULMONARY TUBERCULOSIS.

WE have received a copy of a "supplemental report" of the medical officer of health of the Royal borough of Kensington (Dr. T. Orme Dudfield) on "The Prevention of Consumption and the Sanatorium Question." The report contains many features of interest but we think especial attention should be drawn to the proposal to utilise the "Southern Hospital" at Carshalton for patients suffering from pulmonary tuberculosis. This suggestion is well worthy of careful consideration. It is foolish to collect or otherwise to obtain funds for the erection of new buildings when those already built are suitable. Dr. Dudfield explains that the hospital to which he refers "is a very fine structure," and he adds that it "should be, seeing that it has already cost nearly a quarter of a million and that when equipped for use each of its 800 beds will have entailed an outlay not far short of £375." The hospital was handed over to the Metropolitan Asylums Board in the autumn of 1906 and was intended for patients convalescent from fevers and diphtheria. In November a special committee was appointed "to consider and submit a report as to the best use to which it can be put." Its report, submitted on April 27th, was to the effect that the hospital is not "required for the present." The site is a favourable one for the treatment of tuberculosis. The land lies high, the soil is chalk with a gravel formation, and the area is about 135¼ acres. A large amount of additional land is available should it be deemed advisable subsequently to form a "farm colony." Dr. Dudfield gives a brief description of the buildings. The unit of construction is a single storey double cottage, resembling two capital letters "L" joined together horizontally, the upright stroke representing (for each half cottage) the dormitory and the horizontal stroke the day-room. Each half cottage is constructed for 15 patients and is fitted with all requisite administrative conveniences, an airing court (with a southern aspect, 85 feet by 60 feet) lying between the two dormitories. Of these double cottages there are 24, arranged (*en échelon*) in three groups of four on either side of the central roadway, a "cottage staff block" being attached to each group. By reason of this arrangement sunlight in fine weather falls on every building from sunrise to sunset, no shadow being cast by any one building to the detriment of any other. The lighting, ventilation, and heating arrangements, says Dr. Dudfield, are all that could be desired. The roadways are made but the very ample spaces between the various buildings have not been laid out, and this work alone would occupy many patients for months Dr. Dudfield makes a suggestion which we think might well be considered by those whom it concerns—whether, as in the case of the Benenden Sanatorium, the hospital might not be made self-supporting by a charge for maintenance of, say, 30*s*. per week for each patient? "This for 800 beds would amount to a total of £62,400 (= ⅓*d*. rate), a sum which surely the great friendly societies could well afford to pay if they cared to secure the beds." Dr. Dudfield's report and suggestions should be made widely known and, as we have stated above, they merit close attention and consideration.

THE USE OF DRUGS IN BEVERAGES.

THERE is a curious species of drug habit (for we can call it by no other name) growing up amongst athletes and others made thirsty by drastic exercise which calls for comment. The monotony of drinks or the craze for something fresh no doubt accounts partly for this departure, but we feel sure also that a gradually increasing knowlege of drugs and their uses is a contributory factor. The layman learns that in certain circumstances bitters, for example, do good; they stimulate the nerves of taste and induce reflex effects which serve to aid the digestive process. Appetite is, in short, aroused and a zest for a meal is regarded as a sign of satisfactory health. The drinking of bitters, associated, unfortunately, as it always is, with alcohol in some form, thus easily becomes a habit. The choice of a "bitter" for the purpose is widening, so that now men may be found calling for soda-water and quinine, and the demand is not likely to be refused by the managers of a department which is profitable. Vermuth is the favourite with a good many and a considerable quantity is consumed at golf clubs, the drinker of it being quite unconscious of the fact as described in our text-books that oil of wormwood "is a convulsive poison." We may not unreasonably expect gentian, calumba, chiretta, and so on shortly to be added to these materia medica of the athletes' drinking bar. If this after all does not constitute a drug habit we are very much mistaken. In disease bitters are a powerful aid, for they are tonics, increasing appetite and encouraging the assimilation of food; in health they may easily prove to be mischievous and be productive of evil rather than of good; they will irritate the stomach and induce indigestion. The constant stimulation of healthy glands which act normally without, so to speak, any call for "whipping" must sooner or later lead to fatigue of the digestive organs which might easily bring with it a train of unpleasant symptoms indicating a lowering of the health standard. It is with bitters as with alcohol; both are drugs and the chronic and excessive indulgence in drugs does not, as a rule, help to maintain the normal vigour of the healthy body. When a man finds he cannot distinguish between use and abuse his safe course is to be abstemious.

INFANT MORTALITY AND HOME VISITATION.

THE town of Swinton in Yorkshire has recently taken steps to grapple with the problem of infant mortality which has assumed serious proportions in that locality. Dr. E. English, medical officer of health of Swinton, accordingly decided recently to start a system of house-to-house visiting and instruction of mothers in the principles of baby rearing. As a result of a public meeting, in which the importance of breast-feeding and avoidance of alcohol by nursing mothers was explained and the Huddersfield experiment described, about 20 voluntary workers gave their names to the medical officer of health. It was decided to form a Guild of Social Service to consist of ladies willing to visit among the poor, distributing cards with a few simple instructions regarding the care of infants. This guild held its first meeting at the council's offices last week when the township was divided into districts, each member undertaking a specified district. The president of the guild is the medical officer of health who will meet the workers twice a year and will notify the births to the honorary secretary. A noticeable feature in this scheme is that this work is carried on without any financial aid whatsoever. This is a point worthy of note to small townships which cannot afford the services of a fully trained and qualified health visitor. Another point to be commended to county councils which employ women lecturers on hygiene is the utilising of the services of these ladies to organise similar schemes in outlying townships and villages. We are glad to record the organisation of such public-spirited work and we trust that its success will be such as to induce other districts to follow this excellent example.

INJURY TO THE KIDNEYS DUE TO THE X RAYS.

ABOUT three years ago Albers-Schönberg showed that if the abdominal surface of male guinea-pigs or rabbits was exposed for a prolonged time to the *x* rays sterility but not impotency developed. This was due to azoospermia which was dependent on the disappearance of the epithelium of the seminiferous tubes. Subsequently he showed that the ovary was still more susceptible to the action of the rays. Then American writers, Dr. Tilden Brown and Dr. H. W. van Allen, found azoospermia in men engaged in *x* ray work.[1] The therapeutic action of the rays on the spleen and the lymphatic glands in leukæmia and lymphadenoma and other conditions is now well recognised. In the *American Journal of the Medical Sciences* for May Dr. A. S. Warthin has published an important paper on their action on the kidneys, a subject on which but little is known. In 1904 Linser and Baermann found that exposures of one hour produced transitory albuminuria without apparent changes in the renal epithelium. Dr. Warthin has found remarkable changes in the kidneys in two cases of leukæmia treated with the *x* rays. In one case of the myeloid type the leucocytes numbered 800,000 and the spleen was greatly enlarged. Exposure of the splenic region to the rays twice a week for two months produced great improvement. Daily exposures were then given for seven months and the improvement was so great that hopes of cure were entertained. The patient remained in a good condition for six months, although the leucocyte count was high and there was a large percentage of myelocytes. The treatment was renewed for seven weeks but the patient became worse and died. The necropsy showed changes characteristic of leukæmia only in the retro-peritoneal lymphatic glands. The viscera showed "slight parenchymatous degeneration." In the kidneys were remarkable changes. On cutting the kidney marked grating and resistance were observed. The cut surface showed numerous whitish streaks corresponding to the medullary rays and due to deposits of lime salts which filled the tubules and displaced the renal epithelium. The remaining parts of the parenchyma were atrophic and presented cloudy swelling and fatty degeneration. The intertubular connective tissue was increased and there were localised inflammatory changes throughout the cortex. When the lime salts were dissolved out the epithelium of the affected tubes was found to be completely necrosed. In the other case there was small-celled lymphatic leukæmia, and similar changes were found in the kidneys. Such changes do not appear ever to have been described in leukæmia untreated by the rays. In 25 cases of various forms of leukæmia Dr. Warthin examined the kidneys and found in all more or less extensive parenchymatous degeneration, leukæmic metastases, and localised inflammatory changes, but in none was there any deposit of lime salts or such extensive necrosis as in the cases reported. In another case recorded by Dr. Grosh and Dr. Stone of Ohio the renal epithelium showed advanced cloudy swelling, fatty degeneration, and simple necrosis. Dr. Warthin exposed white mice, rats, guinea-pigs, rabbits, and Belgian hares to the x rays. Small animals were placed entirely in the field of exposure; the larger ones were exposed in the abdominal region (including the spleen and kidneys). Exposure for from half an hour to an hour produced slight nuclear changes in the renal epithelium, swelling of the nucleus, vacuolation, and clumping of the chromatin. After from six to 12 hours there followed a secondary change characterised by albuminuria and cloudy swelling. Exposures of small animals for five hours were invariably followed by paralysis, coma, and death within ten days, a result evidently due to the effect of the rays on the nervous system. In these cases the renal changes were more marked; the renal cells were diminished in size and cloudy and the tubules were distended with an albuminous precipitate.

A COMMITTEE ON DISTEMPER IN DOGS.

THE President of the Board of Agriculture and Fisheries has appointed a committee to inquire into the nature of distemper in dogs in Great Britain and the methods of its infection and to report whether any, and, if so, what, preventive or remedial measures, exclusive of ordinary medical treatment, can with advantage be taken with respect to it. The committee is constituted as follows: Lord Middleton (who will act as chairman), the Duke of Beaufort, Lord Leconfield, Sir John McFadyean, M.B. Edin., M.R.C.V.S., Mr. Edward Barclay, Mr. Stewart Stockman, M.R.C.V.S. (chief veterinary officer to the Board of Agriculture and Fisheries), and Mr. William Musgrave Wroughton. Mr. James Ralph Jackson, M.R.C.V.S. (veterinary inspector, Board of Agriculture and Fisheries, 4, Whitehall-place, S.W.), will be secretary, and the cost of the inquiry will be defrayed by subscription and guarantees, no charge in respect of it falling upon public funds.

THE CARMICHAEL PRIZE ESSAY.

THE President and Council of the Royal College of Surgeons in Ireland give notice that on the first Thursday in November in the year 1908 they will proceed to adjudge a prize for the best essay that may be presented to them in accordance with the well-known instructions prescribed by their famous President, Richard Carmichael. These instructions were:—

> (1) The state of the medical profession in its different departments of physic, surgery, and pharmacy in Great Britain and Ireland at the time of the writing of these prize essays.
>
> (2) The state of the hospitals and schools of medicine, surgery, and pharmacy.
>
> (3) The state and mode of examination or of testing the qualifications of candidates of the different licensing colleges or corporations of medicine, surgery, and pharmacy.
>
> Under these heads the authors will be pleased to make such suggestions as may occur to them respecting the improvement of the profession, with the view of rendering it more useful to the public, and a more respectable body than it is at present. In these suggestions the authors will be pleased to consider the preliminary and moral education of medical and surgical students, as well as the mode of conducting their professional studies.
>
> In considering the third head, or mode of testing the qualifications of candidates by the licensing bodies, the authors will please to consider the most practical mode of rendering the examination as demonstrative as possible—i.e., in anatomy, by having the dead subject placed before the candidate; in chemistry, botany, and pharmacy, specimens of minerals, plants, and pharmaceutical preparations placed before him; and in the practice of physic and surgery, the candidate to be placed before the patients in the wards of an hospital, as the testator is certain that this will afford the most certain and only true mode of ascertaining the qualifications of candidates.

Each essay is to be distinguished by a device or motto, and accompanied by a sealed packet, containing the name and address of the writer, also distinguished by the same device or motto, and must be lodged at the College on or before July 1st, 1908. The authorities of the College have decided that no essay shall exceed 65,000 words in length and all quotations shall be by reference to the volume and page of the work on which the passage desired to be quoted is to be found. The president and council of the College do not consider themselves bound to award the prize, which is of the value of £120, should none of the essays appear to them to possess sufficient merit.

LEAD COMPOUNDS IN YARN.

THE Home Office has recently issued a circular in which certain proposals are made in regard to regulations required to be observed in the process known as the "heading" of yarn dyed by means of a lead compound. "Heading" means the manipulation of yarn dyed by means of a lead compound over a bar or post and includes "picking, making-up, and noddling." The regulations are intended to supersede the existing special rules for factories or workshops in which yellow chromate of lead is used or in which goods dyed with it undergo the process of bundling, or noddling, or other treatment. The chief points in which the proposed regulations differ from the existing rules are as follows: (1) the application of the regulations is limited to the particular process in which the danger of lead poisoning has been found to be serious, as in the case of the "heading" of yarn which has been dyed by means of a lead compound; (2) the requirements in regard to exhaust ventilation for the removal of dust and to the provision of washing accommodation are made more precise; and (3) a periodical medical examination of persons employed on the dangerous process is established. These regulations are issued in draft form and are subject to further consideration, persons affected being invited to enter their objections, if any, within 40 days of the issue of the notice, which is dated June 22nd.

DERMATOLOGICAL SOCIETY OF LONDON.

THE amalgamation of many of the medical societies of London, desirable though it undoubtedly is in many ways, puts an end to the individual existence of the constituent bodies, and especially is this noticeable in those cases where two separate societies unite to form one section of the Royal Society of Medicine. The Dermatological Society of London has lasted almost exactly a quarter of a century, for it was founded in July, 1882, and it has come to an end in June, 1907. In several ways the society has been unique. It has never been a large body, for it has never, we believe, had 60 members; but they have all been men who have been greatly interested in diseases of the skin and the work that the society has done has been of great value. At the time when the society was founded dermatology in this country was in a very chaotic condition and the then new society soon began to bring order out of the chaos. From the first the rule was laid down that there should be no papers read at the meetings and the whole proceedings have always consisted in the exhibition of cases. In this way the society has been of very great educational value to its members, every one of whom has learnt much at the meetings where views were freely exchanged. Much of the present high position of dermatology in this country is owing to the work done by the society. Its original inception was due to Dr. J. H. Stowers who was then working in the dermatological department of St. Bartholomew's Hospital under Mr. Morrant Baker and to Dr. Alfred Sangster, and these were the original secretaries. At no time has there been a President; the chair at each meeting has been taken by one of the members of the Council present. To commemorate the society, as it was about to cease to exist, 18 of the members dined together on June 12th, when Mr. Jonathan Hutchinson occupied the chair, supported by Dr. H. Radcliffe Crocker and Dr. Stowers. Mr. Hutchinson gave an amusing account of the condition of dermatology when he first came to London n 1850. A general feeling was expressed that while all the members regretted the demise of the Dermatological Society of London they were looking forward hopefully to the dermatological section of the Royal Society of Medicine to carry on the good work initiated by the society.

EPIDEMIC CEREBRO-SPINAL FEVER.

DURING the last few days cases of epidemic cerebro-spinal fever have been reported at places in the counties of Northumberland and Durham. In Scotland during the week ended June 22nd there were five deaths from this cause registered in Glasgow, five in Edinburgh, one in Paisley, and one in Leith. In Glasgow the weekly report issued on June 21st showed that there were at that time 87 cases under treatment. In Belfast during the week ended June 22nd there were 20 deaths registered as being due to this cause.

"COMPOUND" OR "BLENDED" WHISKY.

THE Secretary of the United States Department of Agriculture has recently issued a bulletin dealing with the labelling of whisky under the new pure food law. The first aim of this law is to insure, so far as possible, that the purchaser of a food or drug shall obtain nothing differing from that which he wishes to buy. In a secondary way the law also seeks to prevent, or at least to discourage, the use of deleterious substances as food or drugs. Before expressing an official opinion on the labelling of different brands of whisky considerable attention is given to the etymological distinctions between the terms "compound" and "blend." Webster defines a "compound", as "that which is compounded or formed by the union or mixture of elements, ingredients, or parts; a combination of simples." According to the same authority a "blend" is "a thorough mixture of one thing with another, as colors, liquors, &c., a shading or merging of one colour, tint, &c., into another, so that it cannot be known where one ends or the other begins." Thus "blend" and "compound" are substantially synonymous terms when applied to mixtures of liquids in ordinary speech. But the pure food law establishes a distinction between them, based upon the character of the ingredients entering into the mixture, the word blend being defined in Section 8 as "a mixture of like substances, not excluding harmless coloring or flavoring ingredients used for the purpose of coloring and flavoring only." The opinion of the Attorney-General of the United States on the meaning of these words is that the terms "blend" and "blended" can be properly used only when a single substantive, either in the singular or plural number, need follow to designate the combination appropriately and adequately. Thus we can speak of a "blend of teas" or a "blended tea," but not of a "blend of tea and coffee." In applying these terms to whisky consideration is first given to a definition of the term "whisky" which has been approved by the United States Department of Agriculture. "Whisky is a distillate, at the required alcoholic strength, from the fermented mash of malted cereals, or from malt with unmalted cereals, and contains the congeneric substances formed with ethyl alcohol which are volatile at the ordinary temperatures of distillation and which give the character to the distillate." It is held that a mixture of two or more different whiskies, as thus defined, whether their differences arise from the character of the substances from which they were distilled or from their respective methods of distillation or even from their several ages and the environment in which they were kept subsequently to distillation, would be appropriately termed a "blend of whiskies," or "blended whisky," or "blended whiskies," provided that each article entering into the combination, standing alone, would be appropriately designated as "whisky." Further, the mixture of a spirit properly designated as "whisky" with another spirit, such as ethyl alcohol, which, standing alone, would not be properly designated as "whisky," must be labelled as a "compound" or as "compounded." This question has led to an animated dispute owing to the fact that dealers attach much importance to its settlement, involving, as it does, large pecuniary interests. With regard to a mixture of ethyl alcohol, either pure or mixed with water, with harmless colouring and flavouring agents intended to impart the appearance and flavour of whisky, it is held that the product should be labelled "imitation whisky." In conclusion, four specimen labels are given to designate (1) "straight whisky;" (2) a mixture of two or more "straight" whiskies; (3) a mixture of "straight" whisky and ethyl alcohol; and (4) ethyl alcohol flavoured and coloured, so as to taste, smell, and look like whisky. (1) "Semper Idem Whisky": a pure straight whisky mellowed by age; (2) "E Pluribus Unum Whisky": a blend of pure, straight whiskies, with all the merits of each; (3) "Modern Improved Whisky": a compound of pure grain distillates, mellow and free from harmful impurities; and (4) "Something Better than Whisky": an imitation under the pure food law, free from fusel oil and other impurities. It is assumed that both the whisky and the alcohol in the third specimen are distilled from grain. It remains to be seen whether judicial decisions will accept these interpretations, as stated so clearly by the Attorney-General.

THE TREATMENT OF INEBRIATES IN LONDON.

FROM the reply of the Home Secretary to a question put by Mr. Pickersgill, M.P., as reported in the column of Parliamentary Intelligence in our issue of June 15th, it appears that the Government is endeavouring to induce the London County Council to reconsider the decision taken by that body to terminate the arrangement by which habitual drunkards committed from the London police courts have been received into the certified reformatories of the National Institution for Inebriates. If Mr. Gladstone's efforts are unsuccessful and if the Council persists in the retrograde policy which it has adopted, the Inebriates Act of 1898 will, as regards its most important provisions, be reduced to a dead-letter. The Farmfield Reformatory, which is the sole institution of this kind maintained by the Council, can admit only an insignificant number of selected cases, so that in dealing with the bulk of the police-court recidivists, whose prolonged detention under reformatory treatment was the chief social advantage of the Act, magistrates will be forced to return to the costly and futile system of repeated short imprisonments. The immediate effect of this policy in London, where the convictions for drunkenness amount to considerably over a fourth of the total number in England and Wales, will be sufficiently serious, but its indirect influence will be perhaps still more deplorable. Apart from the check to the rational treatment of the inebriate which will necessarily follow from its abandonment by a body of the authority and repute of the London County Council, the operation of the Act in other parts of the country will be paralysed by the conversion of the metropolis into a place of sanctuary where the "drunk and disorderly" need fear no treatment more efficacious, and therefore from their point of view more objectionable, than the time-honoured "five shillings or seven days." It is difficult to suppose that the members of the Council who are responsible for this regrettable decision can have fully appreciated the effect of their action or that when it has once been made clear to them they can still maintain so unreasonable an attitude. Meanwhile it may not be out of place to remark that the episode teaches a very useful lesson for the future. This absurd difficulty would never have arisen if the Act of 1898 had been framed with a little more regard for the limitations of human nature. The legislature, by making over to the local authorities the duty of providing inebriate reformatories or subsidising the reformatories built by private enterprise, while at the same time it abstained from rendering the performance of this duty compulsory, practically put a premium on slackness. It expected that local authorities would undertake of their own free will to maintain out of the rates a class of social undesirables who would otherwise have to be accommodated in prisons supported at the expense of the State. That several county authorities should have had the altruistic enthusiasm needed to respond to this appeal is very remarkable in these days when the cry of the over-burdened ratepayer is loud in the land but it may be doubted whether such enthusiasm can be expected to last. It is to be hoped, at all events, that when the long-promised attempt is made to deal with the vagrancy problem by the method of labour colonies the experiment will not be rendered futile by any blunder of the same kind, and that if the State does not itself provide the funds for the maintenance of such colonies it will at least see that the local authorities who shirk their responsibilities shall not profit financially by their remissness.

THE SALE OF PROPRIETARY MEDICINES IN AMERICA.

IN an address recently delivered before the Medical and Chirurgical Faculty of Maryland Dr. George H. Simmons, editor of the *Journal of the American Medical Association*, dealt in an outspoken fashion with the modern development of the trade in proprietary medicines and the harm done thereby in the United States. This matter was referred to at some length in a leading article in THE LANCET of April 20th. One of the chief charges brought by Dr. Simmons against what he terms the nostrum evil is that a great deal of indirect advertising or advertising through the medical man himself is resorted to in order to push the sale of certain preparations. They are advertised solely in medical journals, but do not conform to the rule of the American Medical Association that such articles should not be labeled with the names of diseases in the treatment of which they are supposed to be employed. Dr. Simmons also insisted on the need for a clear statement as to the composition of any proprietary medicine. He concluded by announcing the forthcoming publication by the American Medical Association of a book in which will be printed trustworthy information in regard to non-official remedies. This book will be supplementary to the American Pharmacopœia and will include only proprietary articles and new drugs that are not in the Pharmacopœia. By open publication of this sort the association hopes to check the evils of self-drugging, but Dr. Simmons points out that without the aid of the medical profession all efforts will be in vain. The council of the American Medical Association is purely an advisory body and there is no law which will compel the manufacturing chemists to recognise its requirements. If, however, medical men will band together and lend assistance to the efforts of the American Medical Association to restrain, at any rate, the inordinate amount of proprietary medicines which is sold in the United States much may be done. Conditions in Great Britain in regard to proprietary medicines are somewhat different from those which prevail in America but the sale of such remedies is increasing by leaps and bounds in this country and perhaps a leaf might be taken with advantage from the book of the American Medical Association. As pointed out in THE LANCET of April 20th the general public need to be educated so far as quack medicines are concerned and the steps taken by the American Association tend in this direction.

THE Nettleship gold medal of the Ophthalmological Society of the United Kingdom has been awarded to Mr. J. Herbert Parsons, F.R.C.S. Eng., for his work, "The Pathology of the Eye." It will be remembered that we reviewed Vol. III., Part I., of this work in THE LANCET of Jan. 5th this year. This is the second award of the prize the institution of which we noticed in THE LANCET of Feb. 20th, 1904. In that year it was awarded to Mr. Priestley Smith, F.R.C.S. Eng. The medal is awarded for the best work on ophthalmology during the previous three years.

AT the next meeting of the Society for the Study of Inebriety, to be held in the rooms of the Medical Society of London, 11, Chandos-street, Cavendish-square, on Tuesday, July 9th, at 4 P.M., Mrs. Mary Scharlieb, M.D., M.S., will read a paper on "Alcohol and the Children of the Nation."

THE annual prize-giving in connexion with the London School of Medicine for Women will take place on Thursday, July 4th, at 4 P.M., at the Royal Free Hospital. Professor W. Osler will present the prizes. Mrs. E. Garrett Anderson, president of the school, will be in the chair.

Dr. Edward Hallaran Bennett, whose death occurred on June 21st last in Dublin, had for a long time been in bad health. He was one of the best known and most scientific surgeons in Ireland and had been President of the Royal College of Surgeons in Ireland.

Dr. C. Theodore Williams, M.V.O., who, as we announced in THE LANCET of June 1st, 1907 (p. 1503), has lately founded a medical scholarship at Pembroke College, Oxford, his old college, has been elected an honorary fellow of that college.

THE INTRODUCTORY GRESHAM LECTURE.[1]

BY F. M. SANDWITH, M.D. DURH., F.R.C.P. LOND.,

GRESHAM PROFESSOR OF MEDICINE.

LADIES AND GENTLEMEN,—My first duty is publicly to express my heartfelt thanks to the Warden and Livery of the Mercers' Company and to the Gresham Committee for the great honour which they have recently bestowed upon me. And as I desire to follow, however unworthily, in the illustrious footsteps of the sixteen eminent professors who have preceded me in this office I think you will agree with me that I cannot do better than imitate those of them who began their course of lectures with an account of our noble benefactor, Sir Thomas Gresham. Unfortunately their orations have not been preserved, but with the aid of the "Life" by Dean Burgon, a late Gresham professor of divinity, and the interesting volumes in the British Museum written by Dr. John Ward, himself once professor of rhetoric in Gresham College, together with the manuscript notes with which he interleaved his own copy of the work, and with the help of other assistance, printed and spoken, I have been able to get some information about the founder of these lectures. And since it is mighty dull to expect a traveller to wander through a picturesque country without turning to the right or left and without occasionally deserting the high road to explore by-paths and alluring lanes, I have thought it well not to confine myself strictly to the life of Sir Thomas Gresham, but to try to give you also a faint picture of the times in which he lived.

The name of Sir Thomas Gresham (1519-1579) is one of the most illustrious memories of the City of London, and, living as he did during the reigns of four English sovereigns, Henry VIII., Edward VI., Mary and Elizabeth, he dates from the time when England was advancing to the proud eminence among nations which she has since maintained. Her progress was due to many causes and among them I may mention that commerce, the source of our national wealth, was then making great strides, the influence of printing was beginning to be felt, and all the arts of peace and war were being carefully promoted. In his country's prosperity Gresham took no mean part, for he was a statesman as well as a merchant. He lived for a short time at a foreign court as the ambassador of his Sovereign, and both at home and abroad he was the chosen companion and correspondent of the famous princes and nobles of his day. His ancestors derived their name from a little village in Norfolk where they had lived for many generations. We have some letters from his great-grandfather, dated from London in the middle of the fifteenth century, and bearing the seal of a grasshopper, the family crest, which you all know can to-day be seen as the weather vane on the top of the Royal Exchange. Sir Richard, the father of our founder, and his uncle, Sir John Gresham, were both knighted by Henry VIII. and were both raised to the proud dignity of Lord Mayor of London.

---

[1] Delivered at Gresham College on May 14th, 1907

As early as the twelfth century Flemish weavers had settled at Worth-Stead, or Worsted, in Norfolk, a town which gave its name to the twisted yarn, and there they taught their trade to the English, who are still famous for worsted goods. In the time of Sir Thomas Gresham's father the wool trade with Flanders had attained its highest prosperity, which probably explains the connexion of this family of merchants with that country. Liberality and benevolence seem to have been characteristics of the Gresham family, for Sir John converted the family mansion at Holt in Norfolk into a grammar school and succeeded in obtaining from Henry VIII. the hospital of St. Bethlem. Sir John was repeatedly employed as the King's agent in Flanders and amassed a considerable fortune in trade. Young Thomas was apprenticed to him and later was made one of the overseers of his uncle's will. Besides many charitable bequests Sir John left £13 6*s*. 8*d*. to the Mercers' Company for a feast, desiring them after dinner to have his soul in remembrance with their prayers.

Sir Richard Gresham, the father of Thomas, became Lord Mayor in 1537 and was a friend of Cardinal Wolsey, to whom he lent money, and also of his successor, Thomas Cromwell. He was a gentleman usher extraordinary to Henry VIII. and at the dissolution of the monasteries by that monarch he obtained for himself no less than five successive grants of Church lands. He strongly advocated the construction of an Exchange, encouraged freedom of trade, and is said to have invented bills of exchange. Three of his letters written during his mayoralty exist, one of which is a remarkable petition to the King pleading the cause of the afflicted and the friendless. With great dexterity he urges the arguments most likely to have weight with the King and best calculated to secure a favourable result to his application. He writes that the poor, sick, blind, aged, and feeble persons, unable to help themselves, have no place where they may be refreshed or lodged until they be helped and cured of their diseases and sickness. "So it is, most gracious Lord, that near and within the City of London, be three Hospytalls or Spytells, commonly called St. Mary's Spytell (Bedlam), St. Bartholomew's Spytell, and St. Thomas's Spytell." He then begs that the King, as supreme head of the Church of England, should direct the mayor and aldermen of the City to have the order and government, both of all the lands and revenues belonging to the said hospitals, and of the ministers within any of them. He cleverly argues that the funds, instead of providing for a small number of canons, priests, or monks, who lived in pleasure, "nothing regarding the miserable people lying in every street," had better be employed in refreshing, maintaining, and comforting a great number of poor, needy, sick, and indigent persons; also that those diseased should be healed and cured of their infirmities, frankly and freely, by physicians, surgeons, and apothecaries, paid only for that purpose, and, finally, that all feeble persons not able to labour should be relieved and all sturdy beggars not willing to work should be punished. He well knew that the surest road to Henry's favour was a willing acknowledgment of his ecclesiastical supremacy and he had the satisfaction of seeing his petition granted, though it was not till the time of Edward VI. that the revenues of the city hospitals were confirmed. His petition, of which I have given you a short abstract in modern language, was probably the first appeal by a Lord Mayor for hospitals.

To-day we are accustomed in this country to a great number of well-appointed hospitals and asylums, every one of which is a credit to the British race; to a system of sick nursing which I can without hesitation say is the best in the whole world; to munificent donations, subscriptions, and legacies for hospital inmates; and last, but not least, to the charitable funds presided over by His Royal Highness the Prince of Wales and the Lord Mayor of London. But it may be instructive to turn aside for a few moments to consider what these three London hospitals were like in the middle of the sixteenth century. There were, and still are, five city hospitals, though only one of them remains on its ancient site, but Christ's Hospital, the well-known school for boys, and Bridewell, are foundations dating from 1553, after Sir Richard Gresham's death. In that year Edward VI. gave over to the city his palace of Bridewell, which stood on the spot where many of our early sovereigns had resided, to be used as a workhouse for the poor and a house of correction "for the strumpet and idle person, for the rioter that consumeth all, and for the vagabond that will abide in no place." This will remind you that the word "hospital" was originally used for a place benefiting any class of persons requiring public help, not necessarily for the sick and injured. The condition of these latter was surely unique towards the end of Henry VIII.'s reign. For the religious foundations, established by the piety of preceding centuries, had cared to some extent for the welfare of the needy, though their enemies vowed that most of the stewards lived rather for their own selfish pleasures. When the religious orders were ruthlessly swept aside and their revenues confiscated by the Crown numbers of cripples, lepers, lunatics, foundlings, and aged folk were cast into the streets to beg for their livelihood. Some, not unnaturally, added thieving to their methods of subsistence and forced their attention by many crimes upon the more respectable citizens, hence the petition to re-found the three existing hospitals and re-endow them with their own revenues.

St. Bartholomew's Hospital

This hospital dates from the Priory built by Rahere, the court jester, in 1102, near the three acres of "Smoothfield," now called Smithfield. Here Henry VIII. burnt the stubborn who denied his ecclesiastical supremacy, more than 200 Protestants perished at the stake in the time of Mary, and Elizabeth burnt some Anabaptists. Besides the sale of oxen, sheep, and pigs this was the great horse market of London. It was famous, too, for that great carnival called St. Bartholomew's Fair, and also for the Cloth Fair, the name of which still exists in an alley running by the side of the grand old Norman church of St. Bartholomew the Great. The rapacity of Henry VIII. caused the hospital to be separated from the Priory, and Dr. Norman Moore says that in 1546 the income of the hospital from its estates was only about £300 a year. But, as we have seen, the citizens petitioned the King against the destruction of the hospital and forced him to restore its estate. It was thus refounded in 1546 for 100 poor and sick and Henry VIII. vouchsafed to endow it from its former possessions to the extent of 500 marks per annum, upon condition that the citizens should be bound for ever to give a similar sum every year. The hospital was then made up of detached houses or groups of houses, intersected by narrow lanes or streets. It stood just outside the wall of London, for the country began at this time just beyond Smithfield, and though houses were beginning to be numerous along the line of Holborn, the green fields did not begin westward until the part was reached where the Gray's Inn-road now is. 12 honorary governors were appointed to manage the hospital and their duties were defined by orders and ordinances, at the end of which occurred these words: "And for your labours and pains ye shall be sure of the reward that God hath promised to all them that succour His members." A matron and 12 unmarried sisters were appointed at a total yearly salary of £78 10*s*. Very careful rules were laid down about their conduct; they were not allowed to leave the women's ward after the hour of 7 in the winter and 9 in the summer, except for some "great and special cause, such as the present danger of death or needful succour of some poor person," and they were warned as much as possible to avoid and shun the conversation and company of all men! Three surgeons, annually paid £20 each, were appointed to see the patients, to decide whether an applicant was curable or not, to the intent that no incurable cases should be admitted to the great let and hindrance of the curing and helping of many others. But at the same time no curable cases were to be rejected for fear of causing great slander to the hospital and the displeasure of God. They were commanded while dressing the patients' wounds to give them faithful and good counsel, advising them to sin no more and to be thankful unto

Almighty God for their present benefits. And above all things, the surgeons were to refuse all gifts or rewards for their services, though they were enjoined to make such offers known to the almoners of the hospital. The porter was told to put swearers or quarrelsome patients or those who refused to go to bed at lawful hours into the stocks after previous warning. Eight beadles were given various police duties, including that of preventing any sturdy vagabond from asking alms within the City of London or its suburbs. They also had to collect the children who had been deserted by their parents. The cost of the patient's diet was fixed at 2*d.* daily, but already the restored hospital was spending a little more than its income and appealing to the charitable for extra funds. When a patient was cured he was not allowed to leave the hospital until he could give thanks upon his knees to Almighty God, and the Hospitaller was to charge him to learn the set thanksgiving without the use of a book. He was then given travelling money and a passport and was expected to betake himself to his birthplace or to his latest residence.

St. Thomas's Hospital.

This hospital was originally dedicated to the honour of Thomas à Becket, the martyr of Canterbury. Though it had some early connexion with the Prior and Canons of a neighbouring religious establishment, St. Mary Ovarie, it was not till early in the thirteenth century that it became possessed of a regular annual revenue which enabled it to do beneficial work. It stood for more than six centuries at Southwark, on the site now occupied by the London Bridge Railway Station. The hospital was well placed to fulfil the charitable purposes for which it was intended, for as the road to Canterbury lay through London, and the only bridge over the Thames was in that neighbourhood, it was ordered by the Bishop of Winchester (Peter de Rupibus) that poor pilgrims to and from Canterbury should be permitted to lodge and board there for the night, and in the event of sickness or lameness should be hospitably provided for till their recovery, when they were to be furnished with alms and provisions to continue their journey. Moreover, there was an abundance of pure air and water, and the building was surrounded by high trees. In 1535 the annual revenue was £309, but three years afterwards, when it was surrendered to Henry VIII., as church property, its yearly income was only £266. At this time it merely consisted of a master and brethren and three lay sisters, who lived in the hospital, where 40 beds were made up for the poor and infirm, who were furnished with food and firing. Between 1538 and 1540 Henry VIII., after having been excommunicated by the Pope, is said to have suppressed no less than 645 monasteries and abbeys, 90 colleges and free chapels, and 110 hospitals of various descriptions. He thus turned adrift some 10,000 monks and nuns and annexed revenues amounting to £32,000 a year, besides the goods and chattels which were valued at £100,000 more. Soon after the seizure of St. Thomas's Hospital in 1538 the citizens of London purchased from the Crown some of its landed estates, producing about £160 annually. In 1551 they again purchased from Edward VI. the manor of Southwark, which included the site of the hospital. The building was then increased to 300 beds, and was reopened in 1552 as "The King's Hospital." The original names of the wards were Isaac, Jacob, Job, Tobiah, Noah, Jonah, King, Abraham, Lazarus, and Susannah. The wards varied in size from 15 to 30 beds. About a month before his death, Edward VI. incorporated by charter the Lord Mayor and Corporation of the City in succession as perpetual governors of the Royal Hospitals, and it was then that this charity received the name of St. Thomas the Apostle. The King at the same time liberally endowed the hospital with estates and presented it with linen from the churches. Southwark at that time was the aristocratic part of the metropolis, and mansions with large gardens probably extended along the river as far as Lambeth Palace. We know that near St. Thomas's were the palace and park of Charles Brandon, Duke of Suffolk, one of Henry's favourites, and this accounts for some names still existing in the Borough, such as Park-street and Maze Pond. The hospital was furnished by benevolent citizens, who gave feather beds, straw mattresses, sheets, blankets, linen and clothes for the inmates, who chiefly comprised wounded soldiers (from the wars in France), blind, maimed, sick and helpless sufferers. Similar officers were appointed as at St. Bartholomew's, the physicians and surgeons receiving £15 each per annum.

According to Mr. Benjamin Golding's "Historical Account" the patients proved difficult to manage, for they took every opportunity of escaping from the hospital to resume their old occupation of thieving. During Queen Mary's reign the citizens held aloof from religious politics and occupied themselves in framing rules for the newly endowed hospitals and in confirming their finances on a permanent basis. They dedicated a portion of the fines levelled on City merchants to the support of the hospitals. The governors consisted originally of aldermen, citizens, and freemen of the City, but it was soon found advisable to extend the dignity to other wealthy people. Every man, therefore, of rank and respectability became eligible for election to the General Court of Governors, after being duly presented and ballotted for. On admission he was expected to make a liberal gratuity to the charity, but it was at the same time understood that money alone would not procure a governor's staff, for the honour was dependent on recommendations of worth and public virtue. The governors possessed the power of inflicting punishments for the better regulation of the patients, and a whipping post and stocks were erected at the hospital. Also, it is said, that immoral women, after being cured of their malady, were privately whipped before they were discharged and were admonished to pursue a better course of life. I have laid some stress upon the religious atmosphere of this and other hospitals, and upon the attempts made to insure devout observance of religion from the patients, because these were by no means characteristics of the general populace at the time we are considering. For instance, in the first year of Mary's reign an Act of Common Council was found necessary to prevent people defiling St. Paul's Cathedral. It appears it was their habit to carry through the church great quantities of ale, bread, fish, meat, and other wares, while some of them irreverently led mules, horses, and other beasts through the building. The various chapels of the Cathedral were converted into warehouses for lumber, carpenters' shops, bakers' establishments, and even a playhouse! All this, as the Act says, was found to be very disturbing to Divine service.

Bethlem Royal Hospital.

The priory of St. Mary of Bethlehem, founded in 1246 by a Sheriff of the City, stood in the parish of St. Botolph without Bishopsgate and was spoken of as a hospital for lunatics as early as 1472. It was seized by Henry VIII. at the general dissolution of monkish houses, but in 1547 it was restored to the mayor and citizens of London as a royal foundation, from which time it again became a hospital for the cure of lunatics. The citizens found it absolutely necessary to confine the mad folk, especially those who had committed crimes, and its retired situation and its proximity to the City marked it out as a fit receptacle for these unfortunates. The patients were chained and exhibited like wild beasts to the public, while those who were partly cured were turned out with badges on their arms to wander and beg in the streets. Edgar, in Shakespeare's *King Lear*, was one of these "Tom-o'-Bedlams." The north side of the Great Eastern Railway station in Liverpool-street is built on the grounds of the original Bethlem Hospital. As the City grew the hospital was removed to the suburb of Moorfields in 1675. Even up to the year 1770 it derived a revenue of at least £400 a year from visitors who came out of curiosity to see the lunatics. This habit was then relinquished because, though beneficial to the funds of the charity, it was thought to counteract its grand design by tending to disturb the tranquillity of the patients! The Moorfields building was copied from the Château of the Tuileries in Paris, and Louis XIV. was so much offended at his palace being made a model for a lunatic asylum that in revenge he ordered a plan of St. James's Palace to be taken for offices of a very inferior nature (Bowen.)

After this long preamble we must return to our patron, Thomas Gresham. He was born in London in 1519, and sent to the University of Cambridge in his youth, where he was admitted a pensioner at Gonville and Caius College. As he was destined by his father and by family tradition to become a merchant it is suggested, not unfairly, by his biographers that he must have shown signs of uncommon ability to have been given the privilege of education at the University at a time when it was usually reserved for those who intended to enter the learned professions. His residence at Cambridge not only confirmed his attachment to the Protestant faith, but gave him a love of literature and of learned men which distinguished him throughout all his life. He was apprenticed for eight years to his uncle and in due time admitted a member of the Mercers' Company. When he was 32 years old King Edward's financial affairs had been so mismanaged that it became necessary to consult several merchants as to the best methods of extricating the King from his difficulties. Gresham was summoned among others and was eventually desired by the King and the Council to take the matter in hand and this necessitated his removal to Antwerp with his family. For many centuries English sovereigns had been in the habit of obtaining loans from opulent merchants in Germany and the Low Countries and of paying very heavy interest. It had therefore been the custom to keep a royal agent, sometimes called the king's merchant or factor, at a foreign court. His duties consisted in raising money for the King by private loans and in keeping the Privy Council informed of whatever was passing abroad, and he was not infrequently called upon to negotiate with foreign princes in the capacity of ambassador. To this office Gresham found himself appointed. It must be remembered that at this period the Low Countries were in the zenith of their prosperity. They yielded to no State in Europe in wealth and splendour and were unrivalled from the commercial point of view. They possessed numerous towns and villages, hamlets which were worth more than many cities in other countries, a soil thickly inhabited and cultivated to the greatest extent, an intelligent people excelling in every elegant and useful art, of which traces to-day remain in the schools of painting and in famous buildings. Antwerp had inherited the trade of Bruges and had become the centre of civilisation and the most conspicuous commercial capital in Europe, and at the time which we are considering it was no uncommon sight to see two or three thousand vessels at one time in the river Scheldt laden with merchandise from every quarter of the globe.

The English merchants were important enough to be given an official residence, where our ambassadors were entertained when travelling and whither the English residents habitually retired in times of danger. The most important article of traffic between England and Antwerp was cloth, and the other goods obtained from England were wool, lead, tin, many kinds of leather, including sheep skins and rabbit skins, beer, cheese, and Malmsey wine, then obtained by the English from Cyprus. The principal exports from Antwerp consisted of jewels and precious stones, bullion, quicksilver, silks, cloth of gold and silver, spices, drugs, sugar, cotton, linen, tapestry, hops, glass, salt fish, arms, ammunition, and household furniture. These brief lists show how highly civilised Antwerp was at this time. Gresham found means to raise the exchange between the two countries from 16 Flemish shillings for the English pound to 22 shillings, and he was thus able to discharge the King's debts, to render money plentiful and trade prosperous, while the credit of the English Crown became established on a firmer basis abroad than it had ever been before. Edward VI. was so sensible of the services thus rendered him that shortly before his death he bestowed upon him valuable lands and said, "You shall know that you have served a king."

Gresham was removed from his office after Queen Mary's accession, but was reinstated within a few months, in order to raise for the Crown £50,000 at 11 or 12 per cent. interest for one year. The Queen showed that her dispositions to him were very friendly, and he tells us that the lands which Mary granted him amounted, altogether, to the yearly value of about £200. He wrote from Antwerp to the Lords of the Council to say that news had reached that city of the birth of a young prince to the English throne, in consequence of which the great bell of the city was rung, the English ships in harbour fired joyous salutes, and the Regent of the Netherlands presented the English sailors with 100 crowns to drink the health of the royal heir. He then inquired anxiously whether the news were true, for he found it odd that none of the English residents had received any letter on the subject. The atmosphere of the English Court was for nearly six months in the greatest excitement and the undiagnosed dropsy of the poor Queen caused gossips to talk of nothing but midwives, nurses, and cradles. Certain loyal subjects even went so far as to describe the beauty of the newly born prince; among these were the authorities of Norwich Cathedral and the incumbent of St. Anne's church within Aldersgate. But by far the most extraordinary circumstance connected with this delusion is little known. There is in the State Paper Office, according to Dean Burgon, an original letter to Cardinal Pole, signed by Philip and Mary, announcing the birth of a prince. "Whereas it hath pleased Almighty God of his infinite goodness to add unto the great number of his other benefits bestowed upon us, the gladdening of us with the happy delivery of a prince." The date is left blank, but the letter is endorsed "29th May, 1555."

On Elizabeth's accession Gresham was confirmed in his post and again despatched to Antwerp to raise fresh loans on bonds guaranteed by the City and to buy ammunition, such as gunpowder, hand guns, pikes, daggers, and bow staves, besides coats and sleeves of mail and helmets. Before he left England he wrote to his new Queen a letter of advice on financial questions, recommending her, among other things, to grant as few licences as possible, to make as few debts as she could outside her own dominions, and last, but not least, to keep her credit, especially with her own merchants, "for it is they who must stand by you, at all events in your necessity." The paternal air with which this merchant of 39 years addressed his sovereign helps to show us the important position which he and others engaged in commercial pursuits had then obtained. The word mercer in ancient times meant any dealer in small-wares but as the commerce of this country became more extended the operations of the mercers assumed a more important character and the words mercer and merchant became nearly synonymous. Sir Richard Whittington was a member of the Mercers' Company and so was the maternal grandfather of Queen Elizabeth, and that great Queen herself honoured the mercers by becoming a free sister. It was during her reign that the mercers added rich silks to the woollen cloths which had up to then been their chief article of traffic. These silks were brought from Italy and sold in the Cheapside, St. Lawrence Jewry, and the Old Jewry.

At the end of 1559 two great honours befell Gresham: he was raised to the dignity of knighthood—a prouder distinction at that time than now—and after being furnished with the necessary letters of credence he was sent with the rank of temporary ambassador to the Court of the Regent of the Netherlands, who was then the Duchess of Parma, half-sister of Philip II. Northern Europe was in a condition of general unrest and Elizabeth's ministers were evidently anxious lest any alliance between Spain and France should cause a descent of combined troops on Leith, which was still in the hands of the French garrison, the remnants of the expeditionary force which had landed 11 years earlier to assist the Scotch in their quarrels with England. We had just made peace with France and had relinquished Calais, our last possession on French soil. The husband of Mary Queen of Scots had succeeded to the throne of France and the persecution of the Huguenots had already begun. Philip II. had replaced his father, Charles V., as sovereign of the Netherlands and had now retired to Spain to brood over his wrongs against England and to concoct, with the Inquisition, means for re-converting the Protestants of this country into Papists. The sails of the Grand Armada were already rising on his mental horizon. He was then on the eve of his second marriage with the daughter of Henry II. of France. He had made Spanish rule, with its accompanying inquisition, extremely unpopular in the Netherlands, where a handful of nobles were preparing for the open rebellion which culminated in the throwing off of the Spanish yoke and the establishment of a free, strong, and prosperous Commonwealth in the Low Countries.

Gresham found increased difficulties in exporting gold, gunpowder, and ammunition to the Tower of London, and in his letters urged great secrecy upon Lord Burghley; he also had to bribe the officials in Antwerp to get his goods safely on board. He duly reported to his chiefs that Philip was accumulating shiploads of gold and silver in Spain from the new world, and he points out England's unreadiness for the war which he foresaw must be coming. Among other things he advised the erection of gunpowder mills to prevent this country from being wholly dependent on foreign supply, and he emphasised the importance of keeping Her Majesty's ships and sailors ready armed for war. At one time he seems to have received information that an invasion of England might be expected any day and he recommends that special attention should be paid to the Isle of Sheppey, to Queenborough Castle, Dover and its neighbourhood, and Portsmouth and the Isle of Wight, for these were places where the French were most desirous to land. Spain was another quarter from which an attack might be expected and he emphasises the fact that Her Majesty's ships at Chatham had only five pieces of mounted cannon on shore to defend them. The relations between England and the Netherlands became more and more strained, but Gresham retired to live in London before anything like an open rupture took place. His business residence was in Lombard-street, which was then the handsomest street in London, and, like all other bankers and merchants, he kept a shop, and over his door was his crest, the grasshopper, by way of sign. Although he was a mercer and merchant-adventurer, his chief business was probably that of usurer, pawnbroker, goldsmith, and dealer in bullion. 10 or 12 per cent. was the customary rate of interest during the reign of Queen Elizabeth, and there was then no such thing as the modern banker, whose business is, of course, of quite a different description. I have purposely used the word *shop* because even to this day the word survives as the outer part of Child's well-known banking establishment to distinguish it from the inner counting-house and office. In such a shop as Gresham's all sorts of gold and silver vessels were exposed for sale, as well as ancient and modern coins, and at the period of his death a considerable portion of his wealth consisted of gold chains. It is an interesting circumstance that Lombard-street has retained both its character and its name for more than six centuries, and if you take the trouble to-day to count the banking houses you will find that there are more than a dozen in that short street. When the Jews had been dismissed from England they were succeeded by the Lombards, which was the general term for Italian merchants from the four republics of Genoa, Lucca, Florence, and Venice. In process of time they became the richest merchants and the greatest moneylenders in England. Various commercial terms in daily use remain with us as a legacy from them, such as debtor and creditor, cash, bank and bankrupt, &c. Perhaps I may also mention that the £ *s. d.* of constant use has its origin in the Italian words lire, soldi, and denari.

After his knighthood Gresham moved his residence to a more aristocratic locality and fixed on Bishopsgate-street, where he built himself a large mansion to which he gave the name of Gresham House. It was surrounded by spacious gardens and Stow says that it was built of brick and timber, not far from the fresh water conduit which was just within Bishop's Gate. He also says that there were in the street "many fair tenements, divers fair inns, large for the reception of travellers, and some houses for men of worship." On the other side of the street stood Crosby Place (now a restaurant), then inhabited by Alderman Bond who had just built a turret on the top of it. Outside Bishop's Gate was the town ditch, deprived of water, and a receptacle for offal, so that we can imagine the conditions of that day were highly insanitary. As now, there stood the small church of St. Ethelburga Virgin and also Little St. Helen's, so named because it belonged to the nuns of St. Helen, and here there were seven almshouses for the poor belonging to the Company of Leathersellers; and then came St. Helen's Church, or Eastminster, which mercifully escaped the great fire of 1666, and is therefore well known to you all.

Throughout the sixteenth century the plague, or black death, was a permanent form of disease on the European continent, and almost every year there was an epidemic of it in some country. In the summer of 1563 the malady was brought to London by our soldiers from Havre, and Gresham, with many others, fled with his family to his country house. The epidemic was enough to terrify the bravest, for about 1000 persons died every week, and even the Lord Mayor's banquet had to be given up. The old chronicles tell us that during seven months of that year no less than 23,000 persons died in London from plague alone. Stow says "the poor citizens of London were this year plagued with a three-fold plague; pestilence, scarcity of money and dearth of victuals: the misery whereof were too long here to write. No doubt the poor remember it; the rich by flight into the country made shift for themselves." The following year Sir Thomas Gresham lost his only son and determined to devote some part of his great wealth to building a burse at his own expense for the accommodation of London merchants, provided that a site could be found on which the edifice might be conveniently erected. For at least 300 years it had been the habit of merchants to assemble twice a day in Lombard-street, at noon and at six, for the necessary transaction of their business and here they were, of course, exposed to the inclemency of the weather among other inconveniences. As one of the contemporary writers said, they were more like a body of pedlars than respectable merchants. The spot selected was where the present Royal Exchange stands, and in order to clear the site some 80 houses were purchased by the citizens and then razed to the ground. The burse at Antwerp was taken as a model, the architect, many of the workmen, and some of the material also came from Flanders, and everyone worked with such expedition that the building was ready within two years. A little later Queen Elizabeth and her Court came one day from Somerset House, where she was then living, entered the City in state at Temple Bar, and passing through Fleet-street and Cheapside by the north side of the burse, through Threadneedle-street, she reached Sir Thomas Gresham's house in Bishopsgate-street where she dined. After dinner she entered the burse on the south side and inspected it thoroughly, and then she caused the burse by herald and trumpet to be proclaimed the Royal Exchange, and so to be called from henceforth. In less than 100 years this Exchange was totally destroyed by the Great Fire of London. Charles II. laid the foundation of the second Exchange the year after the fire, but this also was burned down in 1838. The third Royal Exchange was opened by Queen Victoria in 1844, and for the first time in history was covered in by a glass roof some 22 years ago, after a petition of the merchants to the Mercers' Company. Among the historical paintings which now adorn the ground floor of the building is one of Queen Elizabeth being received by Gresham on the day she christened the Exchange; this was painted by Ernest Crofts and presented in 1899 by the Mercers' Company.

The original Exchange had a huge grasshopper stationed over each of the four corners of the building, and this insect was also to be seen glistening on the summit of the square tower near the south entrance. There is evidence from many travellers that the building was the finest of its kind in all Europe. Pepys tells us in his diary that after the Great Fire had subsided the statues of the kings of England beginning with William the Conquerer were found to be displaced and only one statue remained in its niche—that of Sir Thomas Gresham. Stow says that the first Exchange obtained the name of "The Eye of London." The upper walk, or pawne, as it was called, was frequented by gallants and ladies of fashion, which will not appear so strange when it is remembered that at that time Barbican, the Minories, and the purlieus of Smithfield were inhabited by the chief nobility of the land. At the end of Elizabeth's reign there were complaints of the entrance to the Exchange being beset by "ratcatchers, sellers of dogs, birds, plants, trees, and other things, to the great annoyance and trouble of merchants, gents, ladies, and others" resorting there. Cornhill and the neighbouring streets were filled all day long with apple-women and orange-women who kept up a constant cursing and swearing against the unruly boys who never ceased shouting. Moreover, whenever there was to be any bull-baiting or bear-baiting the animals were brought in front of the Exchange and there proclamation was made by trumpeters of the hour when the performance would begin.

Sir Thomas Gresham died of apoplexy in 1579 and was buried in St. Helen's Church, where his tomb and memorial window may now be seen. I must reserve for a future lecture an account of the Gresham College which he founded.

THE FIRST REPORT OF THE ROYAL COMMISSION ON MINES.

THE Royal Commission on Mines was appointed on June 7th, 1906, to report on certain questions relating to the health and safety of miners and to the administration of the Mines Acts. The Blue-book which has just been issued as the first report of the Royal Commission is a valuable and interesting document. Owing to the number of questions referred to them and their importance the Commissioners at an early stage of their inquiry limited their investigation to two matters—viz., first the compulsory watering of roads in dry and dusty mines upon which they expect soon to be in a position to issue a statement; and secondly, the provision and use of breathing appliances in connexion with the question of facilitating the work of rescue in the event of an accident—which forms the subject of their first report. Breathing appliances designed to enable persons to remain in a poisonous or irrespirable atmosphere have long been in existence and were applied to practical uses in this country as long ago as 1881 when the "Fleuss" apparatus was employed in connexion with the explosion at Seaham Colliery, Durham. The question of the use of such appliances was referred to the Royal Commission on Accidents in Mines (1880–86) which recommended that arrangements should be made for the establishment of centres in mining districts where additional appliances for succour and relief and special appliances for exploring purposes should be maintained in an efficient condition. Nevertheless, little attention was given to the matter in this country for some years and mining engineers, on the whole, regarded discussion of their general introduction as of theoretical interest rather than of practical value. In 1900, however, an experimental gallery* for testing life-saving apparatus was constructed by Mr. Garforth at Messrs. Pope and Pearson's Altofts collieries, which was apparently the first of its kind either in this country or on the continent, its object being to accustom men to the use of the apparatus under conditions such as are likely to occur in the mines. In 1902 the first rescue station was instituted at Tankersley in South Yorkshire, and it is understood that steps are being taken to erect several similar stations in different parts of the country. On the continent breathing appliances have attracted greater notice and received more general recognition. Their provision is compulsory in Austria, while in Germany many of the larger collieries are supplied with them, although no Government compulsion exists. The matter has quite recently achieved general notice owing to the occurrence of serious explosions at Courrières in France, Wingate Grange in England, and Reden in Germany. The visit of the Westphalian Rescue Corps to Courrières drew public attention to the use of these appliances, and as a result a decree was issued in April of this year by the Minister of Public Works making the provision of breathing appliances compulsory in French coal mines.

In view of the practical importance of this question the Royal Commission carried out a series of chemical and practical tests under laboratory conditions of some of the better-known appliances. The experiments were made for the most part at the Lister Institute by Dr. A. E. Boycott on behalf of the Commissioners, one of whom, Dr. J. S. Haldane, was present at, and took part in, many of the experiments. The forms of appliances selected for investigation were two types of the "Pneumatogen," the "Draeger," the "Shamrock," the "Fleuss," an improved "Fleuss," the "Weg," and the "Aerolith." In principle these breathing appliances fall into one or other of four types—first, a helmet like the ordinary diver's helmet, through which a constant current of air is driven from a pump or compressed air reservoir connected with the helmet by a long length of hose. Such an apparatus obviously limits the distance to which the wearer can go, so that it would evidently be of but little value in rescue work. In the second type the wearer breathes into and out of a bag provided with means for absorbing the carbon dioxide of the expired air, oxygen being supplied from a steel cylinder in which it has been compressed. To this type the "Shamrock," improved "Fleuss," "Draeger," and "Weg" belong, the latter possessing an ingenious contrivance by which the rate of supply of oxygen is regulated to the rate of consumption. In a paper which we publish in this week's issue of THE LANCET Dr. T. Oliver refers to some of these appliances and gives an illustration of the "Weg" apparatus, with some interesting remarks on its use and application in rescue work. In the third type, to which the "Pneumatogen" apparatus belongs, the expired air passes through a cylinder containing super-oxide of sodium and potassium, which absorbs the carbon dioxide and at the same time liberates oxygen. In the fourth type the air is supplied to the wearer by the evaporation of liquid air, the "Aerolith" apparatus being the only one of this variety investigated.

The greater part of the Blue-book is occupied by the Appendix, written by Dr. Boycott, describing the various apparatus, and giving the results of his experiments with them. This appendix is illustrated by photographs and diagrams of the breathing appliances.

Some general considerations of practical importance precede the actual records of the experiments. The apparatus must be air-tight, especially if irritating vapours, such as thick smoke, have to be entered. The amount of oxygen required at rest is 0·3 litre per minute, that during severe exertion two litres per minute, while the activity of walking at the rate of three miles an hour necessitates rather more than one litre per minute. In all forms of the apparatus it is necessary to have a moderately distensible bag to breathe into and out of, as inspiration or expiration against even slight pressure is distressing. Dr. Boycott carefully describes each apparatus and records his experiments with them. He concludes his report with a general consideration of his results. He states that the small "Pneumatogen" (Type I.) apparatus is very light and portable and should be of great value for undertaking short journeys into bad air. The other appliances which are designed for longer expeditions and to enable severe muscular exertion to be undertaken he compares in a table from which it can be seen that although several of them are satisfactory in many ways there is room for improvement in all of them. To give examples, in only two of them, the "Fleuss" and the "Weg," is the gauge indicating the quantity of oxygen remaining in the cylinders visible to the wearer; in the improved "Pneumatogen" the lightness in weight (14½ pounds) is counterbalanced by the poorness of the supply of oxygen and by the resistance to breathing offered by the cartridges of peroxide of sodium and potassium. The "Shamrock," though in many ways well designed, is seriously at fault in regard to the absorption of carbon dioxide. The "Aerolith" affords no good indication of the amount of oxygen remaining for use and there is likely to be a difficulty in the supply of liquid air. The "Draeger" apparatus, though good in regard to the supply of oxygen and the absorption of carbon dioxide is heavy and badly hung and suffers from various minor, though probably remediable, defects. In view of these observations the Commission regards the general results as satisfactory and hope that the criticisms made will lead to improvements. The appliances are in the experimental stage and doubtless extended use will lead to practical advances, a fact already illustrated in the experience of Mr. Garforth with the "Weg" apparatus in the experimental gallery. The Commission is of opinion that the question is ripe for further development in this country and demands the serious attention of the industry. The Commissioners, while deprecating any exaggerated expectations as to the utility of such apparatus in saving life in mines, points out various circumstances in which they may prove to be of value apart from actual rescue work, such as rendering it possible to explore the seat of a gob-fire and to deal with it, which would otherwise be impossible, owing to the smoke, and in a report of a visit to the Westphalian coal-field it is pointed out that the pecuniary saving effected resulting from the use of breathing appliances in such matters has been an important factor in their general adoption. In regard to their use in rescue work after explosions, the Commission is of opinion that they can only play a subsidiary part but that this part may be of considerable importance, especially in facilitating exploration of the mine and reaching men overcome by "after-damp." It is recognised that their use is at present not entirely free from risk in inexperienced hands or when the necessary precautions are not taken, but the risks are less than those of ordinary rescue operations without such apparatus and they can be reduced to a minimum by proper training—a point upon which the Commission lays special emphasis. To this end it recommends the establishment of "central rescue stations" for the joint use of several neighbouring collieries, where selected men should be given thorough instruction in the construction and use of the appliances with practical experience of their use in experimental galleries, such as that made at the Altofts collieries. The Commission considered the question as to the desirability of rendering the provision of these appliances compulsory and it came to the conclusion that sufficient advance has not been made in this country to justify such a recommendation. It recognised the readiness of mineowners in the United Kingdom to adopt any precautions likely to lead to a diminution in the risk of mining. Such a view seems to us a wise one, for whereas compulsion would probably tend to perpetuate the experimental form of such apparatus, more especially if any particular form were recommended, private enterprise is likely to lead to improvement and advance, while public opinion would deal harshly with any mineowner who neglected to provide all the means in his power to safeguard his employees from risk.

The report, with its appendices, should prove of the greatest value, especially to mineowners and those engaged in working at the various forms of apparatus with a view to their improvement. It also forms an authoritative statement of the present position of matters in regard to the subject of which it treats.

DECENNIAL SUPPLEMENT FOR 1891-1900 TO THE SIXTY-FIFTH ANNUAL REPORT OF THE REGISTRAR-GENERAL.

Part I.

Among the various statistical contributions to State medicine periodically issued from Somerset House there is none that is looked for by our profession with greater interest than is the publication before us, which presents, in a concise and instructive fashion, the vital history of England and Wales in the decennium last ended.

The present supplement—which is the fifth of a series, the first number of which related to the ten years 1851–60, and was presented to Parliament in 1864—is divided into two parts; the first part relates to general mortality and its principal causes in the ten-year period ended 1900; whilst the second part, which is promised towards the end of the current year, will deal with the mortality of occupations as observed among the English people in the three years 1900–01–02.

The report before us is the work of Dr. John Tatham, of the General Register Office. Like its several predecessors, it appears in the form of a letter officially addressed to the Registrar-General. The volume contains a preface by Sir William Dunbar, transmitting the report to the President of the Local Government Board for presentation to Parliament.

Although particulars of English mortality in each year had been previously published in the Registrar-General's successive reports, nevertheless the present volume is very much more than a mere summary of those reports. For in its preparation the rates have been re-calculated on revised estimates of population based on the Census enumeration of 1901, and the mortality from various causes in 1891–1900 has been compared with that observed in corresponding periods in the latter half of the nineteenth century. Moreover, advantage has been taken of the Census results to construct two new English life-tables, both of which will be found in the present volume.

In spite of what has been termed the increasing "urbanisation" of the population in recent times the fact that the public health of the country has steadily improved since the passing of the first Public Health Act has been frequently commented on in the reports of the Registrar-General. But the completion of a half century affords a fitting opportunity for a retrospect of whatever life-saving has been achieved within that period. Nevertheless, Dr. Tatham prudently utters a caution against the tendency prevailing in some quarters to attribute to the results of sanitary administration alone the whole of the saving of human life which has undoubtedly taken place and which is represented statistically by a falling death-rate.

A novel feature in this report is the insertion of a series of carefully drawn charts which illustrate graphically the fluctuations of mortality through a long series of years, the curves having been based on the age and sex constitution of the population in 1901. From the first of these charts we learn that the death-rate of the English population in 1838 was 21·7 per 1000 living at all ages and of both sexes, whilst in 1905 the rate was 15·2 per 1000, a decrease of little less than one-third part in the course of that interval.

But even a cursory examination of the chart referred to and of the accompanying tables will suffice to show that the fall in the death-rate has not been by any means uniform throughout the last half century. In the course of that period very considerable changes have occurred in English mortality, and this not only at all ages in the aggregate but at almost every stage of life. For example, in the ten years 1881–90 the general mortality had been at the rate of 18·7 per 1000 living, whilst in the ten years ended 1900 the rate was 18·2 per 1000. Therefore, in the decennium last ended the fall amounted to less than 3 per cent., whereas in 1881–90 it it had been nearly 9 per cent., as compared with the rate in the decennium preceding that period. The foregoing are revised death-rates; the figures at all ages having been corrected for age and sex differences of the living may be accepted as approximately correct. But if we take an example from among the crude death-rates we find that, e.g., in the decennium 1841–50 the mortality, calculated without reference to the ages of the living, was in the proportion of 22·3 per 1000. Bearing in mind the extreme variations of mortality with age, it may be stated that if the number of the living at the several age groups had been proportionally the same in that decennium as they were in 1891–1900, the death-rate at all ages in the earlier period would have been 21·7 per 1000 instead of 22·9, the crude or uncorrected death-rate formerly published.

On comparing the decennium last ended with its immediate predecessor we find that the fall in the death-rate has been shared by both sexes, the rate for males at all ages having fallen by 2·4 per cent. and that for females by 3·4 per cent. Except among old people and young children there has been a decrease of mortality at all stages of life. But it is a significant fact that the decrease in the mortality of young children, which had continued throughout the previous 20 years, has given place to an increase, although of small amount, in the decennium last ended.

For the purpose of estimating the effect of changes of mortality at different ages in successive periods of time the life table method is now generally accepted as the most trustworthy. Accordingly, two new life tables have been constructed for the present report—the one based on the mortality of England and Wales in the ten years 1891–1900, and the other on the mortality in selected health districts in the same period.

The construction of life tables is attended with some difficulty. If it were possible to obtain, in addition to the number of births, an accurate record of the numbers reaching certain stated ages, it would be a simple process to calculate the chance of living from any one age to any other—as, for example, from the beginning of one year of life to the beginning of the next; and these chances or probabilities of living one year would constitute a set of fundamental values from which the other details of the life table could be readily obtained. Such data, however, are not available, so that it is necessary to resort to the population and deaths tabulated in groups of years of life in order to calculate the chance of living one year. A further difficulty arises from the mis-statements of age that are known to exist both in the Census returns and in the death registers. The nature and extent of these mis-statements are fully discussed in the general report of the last census. Probably the causes tending to produce mis-statements in the Census returns may tend in some degree to similar mis-statements in the death registers. A common source of error—that of stating ages in round numbers or in multiples of ten years—can be overcome by grouping the data in periods of life of which these round numbers are the centres. From a very early date this method, which eliminates much of the error due to mis-statement of age, has been adopted in the annual reports of the Registrar-General. Other errors doubtless exist—such as those due to the statement of age at the next birthday instead of that at the last birthday, to over-statement of age in the case of old people, or to inaccurate statement in the case of persons at earlier ages; but the elimination of such errors cannot be effected with certainty.

In this report the changes of the death-rates in recent decennia are shown for males and females separately. Compared with 1881–90 there was an increase in the last decennium of nearly 2 per cent. in the mortality of children of both sexes under five years, as well as a slight increase among males, aged from 55 to 65 years, and among females, aged from 65 to 75 years. At all other age-groups the death-rate has declined, the decrease being especially marked in the age-group from 5 to 35 years. The net result of these changes is a reduction of 2·4 per cent. in the male and of 3·4 per cent. in the female mortality, computing the rate at all ages in the preceding decennium according to the age constitution of the mean population in 1891–1900.

The *life tables for males show that according* to the mortality of 1838–54 a million males born would be reduced to half a million in the forth-fifth year of life; by the table for 1871–80 this amount of reduction is not effected until the forty-eighth year; and, by the table for 1881–60, not until the fifty-second year. By the new table the same amount of reduction is reached in the fifty-third year of life. At the end of the first year of age the survivors are fewer by the new table than by any of the previous three tables. This follows in consequence of the increased infantile mortality in the recent decennium, to which further reference is made at a later stage of the report. At ages after the first year the mortality declines considerably and from the eighth to the twelfth year of life the survivors by the new table slightly exceed the survivors by the table for 1881–90. From age 12 to age 24 the survivors by the new table are somewhat fewer than by its predecessor, but from age 25 onwards the survivors by the new table are again in excess. By the new table the average lifetime of males, or the mean expectation of life at birth, is 44·13 years; this is 4·22 years more than in 1838-54, 2·78 years more than in 1871-80 and 0·47 year more than in 1881-90.

The life tables for females show that whilst by the three earlier tables a million female children were reduced to half a million in the forty-seventh, fifty-third, and fifty-seventh year, respectively, that amount of reduction by the new table was not reached until the fifty-eighth year. As in the case of males, the survivors at the end of the first year of life are fewer by the new table than by either of the previous tables. They are likewise fewer than in 1881-90 until the twenty-fifth year, after which they are in excess at every age.

The expectation of life at birth, which by the three preceding tables had been 41·85, 44·62, and 47·18 years, is increased by the new table to 47·77 years. There is, therefore, an addition of 0·59 year of life owing to the lowered rate of mortality in the recent decennium. At the end of the first year the addition amounts to 1·29 years, at the end of the second year to 1·16 years, and at the end of the third to 1·03 years. After this age the excess falls, until it is only four-fifths of a year at ages from six to eight years, when it again rises, and exceeds one year at ages 14 to 20. It then gradually falls until at ages from 55 to 70 years the expectation is practically the same by both tables. After age 70 the expectation in 1891-1900 is again in excess by amounts increasing gradually with the advance of age. Here also the remarks as to faulty statements of age apply equally as in the case of males.

(To be continued.)

MEDICINE AND THE LAW.

The Diagnosis of Pathological Drunkenness.

A CASE tried last week at the Old Bailey, in which Mr. Justice Bigham imposed the extremely lenient sentence of three months' imprisonment on a man who had attempted to murder his mistress in what he alleged to be a state of alcoholic automatism, illustrates very strikingly the tendency apparent in forensic practice of late years to depart from the stricter rule formerly enforced and to recognise that the mental state of certain drunken offenders may properly be regarded as a condition qualifying the degree of their criminal responsibility. Ordinarily, as in the case just referred to, this question arises in connexion with the peculiar dreamy state which is induced by alcohol in certain predisposed individuals, and which has many analogies with the disorder of consciousness often observed in epileptics as the sequel or the equivalent of a convulsive attack. The diagnosis of this condition, when due to an abnormal reaction to alcohol, is frequently a matter of some difficulty, for an individual in the dream-state may show very little evidence of mental confusion, so that it may readily happen that such incoherence as he does exhibit will be set down to the influence of a moderate degree of normal intoxication and his subsequent profession of loss of memory will be received with incredulity. On this account much interest attaches to the alterations of the reflexes, which have been recently described as characteristic of pathological drunkenness. According to Hans Gudden (*Neurologisches Centralblatt*, No. 23, 1900), whose views have been confirmed by other observers, in a large proportion of cases during the phase of alcoholic automatism there is a loss, or a very marked diminution, of the pupillary reaction to light. It is true that a similar alteration of the light reflex is met with also in profound degrees of ordinary intoxication, but this circumstance hardly detracts from the value of the sign, since it is with the slighter and not with the more pronounced conditions of normal drunkenness that pathological intoxication is liable to be confounded. Of possibly greater importance, because apparently of more constant occurrence, is the alteration of the deep reflexes, which has been described by Kutner. In a series of observations published in the *Deutsche Medizinische Wochenschrift* of July 14th, 1904, he has found that the knee-jerk and the reflexes of the triceps and the tendo Achillis are lost or greatly diminished in the alcoholic dream state and that there is also a marked decrease of muscular tones expressed in an abnormal degree of passive mobility of the limbs. After the deep sleep which, either naturally or as a result of the administration of sedatives, ordinerily terminates this phase of disordered consciousness, the reflexes regain their normal activity or are somewhat increased. It is to be noted, however, that in all Kutner's patients an epileptic tendency constituted the special predisposition to pathological drunkenness, and further evidence is therefore needed before we can be sure that a like condition of the reflexes is found also when the abnormal reaction to alcohol depends upon other causes. In any case the positive value of these signs is sufficient to suggest the desirability of an examination of the reflexes in all cases where a person accused of serious crime possibly connected with drunkenness is seen immediately after the alleged offence.

The Legal Rights of Unborn Children.

The general rule of law is that a possible interest of an unborn child is safeguarded. The application of this principle usually arises in the administration of an estate where a husband or father dies leaving a female beneficiary *enceinte*. Occasionally in this connexion exceptional circumstances arise and have to be dealt with by the courts. Thus in September, 1902, in a Canadian court the mother and her unborn child were given equal interests in an insurance fund which vested on the decease of the husband. Several similar cases have arisen under Section 7, Subsection 2, of the Workmen's Compensation Act, 1897, where a workman has died leaving his wife with a claim under that Act. In February, 1904, in the case Sarah Day *v.* Guardian Assurance Company, tried at Boston County Court, the judge directed that an equal part of the compensation fund should be deposited in a bank for the benefit of the expected child, for it was to be regarded as being dependent on the income of the deceased; further, if the child were not born alive the whole fund was to be payable to the widow. The following are the facts of another case which has recently come before the Master of the Rolls and two other judges in the Court of Appeal. The case is cited as *Margaret Williams (widow) v. Ocean Coal Company, Limited*. The deceased was a quarryman who for long intervals lived away from his wife. The couple met for a short time on Dec. 21st, 1905, and as a result a girl was born on Sept. 21st, 1906, several months after the husband had died. The county court judge at Pontypridd, sitting as arbitrator under the Workmen's Compensation Act, 1897, decided that on the facts produced the wife, and hence *a fortiori* the posthumous child, were not dependent on the deceased man. This decision was reversed upon appeal, where it was held by the three judges not only that the widow had been technically dependent but also that a posthumous child is also a dependent upon the earnings of a workman within the meaning of the Act. This is a point in clinical jurisprudence which it may be useful for medical practitioners to recollect.

BRITISH MEDICAL BENEVOLENT FUND.

AT the recent monthly meeting of the Committee 15 applications for assistance were considered and grants amounting to £155 were voted in relief. It was decided that in future the monthly meeting should be held at 4.30 in the afternoon instead of at 4 o'clock as in the past. Appended is an abstract of the cases which were helped.

Daughter, aged 61 years, of late M.R.C.S. No income; endeavours to support herself by needlework but is in very indifferent health and has injured her right arm. Relieved 15 times, £116. Voted £12.

Widow, aged 35 years, of M.B., C.M. Edin. Quite unprovided for at recent death of husband after an illness of many months' duration which exhausted his savings. Two children, aged 16 and 11 years. Voted £12.

Widow, aged 60 years, of L.R.C.P., L.R.C.S. Edin. No income; has endeavoured to support herself by taking boarders, but now, owing to failing health, is dependent on a daughter who is an elementary teacher. Voted £10.

Daughter, aged 45 years, of late M.R.C.S. No income, and health so bad that regular occupation is impossible. Voted £12.

Daughter, aged 39 years, of late L.R.C.S. No income; unable to make any attempt to earn a living on account of permanent ill-health. Dependent on mother whose income is so small that necessary nourishment cannot be provided. Relieved six times, £50. Voted £12.

Daughter, aged 55 years, of late L.R.C.P., L.S.A. Mental condition prevents employment; has been supported hitherto by a sister who has to earn her own living and whose health is now broken down. Relieved twice, £20. Voted £12.

Widow, aged [illegible] years, of L.R.C.P., L.M. Edin. No income; endeavours to maintain herself by letting lodgings. Children unable to help. Relieved nine times, £105. Voted £10.

Widow, aged 44 years, of L.R.C.P., L.R.C.S. Edin. No income; slight help from children; has just opened a small school. Relieved three times, £36. Voted £12.

Widow, aged 46 years, of L.R.C.P., L.R.C.S. Edin. Only income £20 a year. Six children, four being partially dependent and the others unable to help. Relieved four times, £40. Voted £10.

Daughter, aged 47 years, of late M.R.C.S., L.S.A. No income; suffers from a severe form of epilepsy and consequently unable to follow any employment. Relieved four times, £48. Voted £12.

Widow, aged 56 years, of M.B., C.M. No income; earns a little by needlework and is assisted by only son earning less than £1 a week Health indifferent. Relieved four times, £48. Voted £10.

Widow, aged 55 years, of L.R.C.P., L.R.C.S. Irel. Since husband's death has partially supported herself by maternity nursing but is now nearly blind and has no means whatever. Relieved 13 times, £113. Voted £12.

Daughter, aged 66 years, of late M.R.C.S. Only income a pension of £20 from the Royal Hospital for Incurables; endeavours to supplement this by letting lodgings but has had her rooms empty for some time and is consequently in arrears for her rent. Relieved eight times, £73. Voted £5.

Widow, aged 59 years, of M.D. Edin. No income; lets lodgings but has been very unsuccessful lately. Children unable to help. Relieved three times, £36. Voted £12.

Looking Back.

FROM

THE LANCET, *SATURDAY*, June 27th, 1829.

PRESERVATION OF LEECHES IN WINTER.

THE following singular plan is adopted among the Siberian tribes of Russia for preserving leeches during the winter season. If the statement in which the account is given (*Graefe's Journal*) be correct, and the authority is high, the mode appears, as far as practicable, to be worthy of imitation, as so much complaint is made of the difficulty it is intended to obviate. In October, a pit is dug, in marl or clay, in the open air, and the sides and bottom are made perfectly hard and smooth; it is then filled with fresh river water, the leeches are placed in it, and the whole mass of water is allowed to freeze to solidity. Whenever any of the leeches are required, a piece of ice containing them *is chopped out of the pit*, and is allowed to thaw gradually in a cool place. The leeches do not injure by this freezing, but will bite with greater readiness than those kept in a room during the winter.

SINGULAR TREATMENT OF TETANUS.

THE following extraordinary practice for the cure of this disease prevails amongst the inhabitants of the Tonga or Friendly Islands in the South Pacific Ocean, among whom it is said, that traumatic tetanus prevails to a great extent. It consists in producing a considerable degree of irritation in the urethra, and discharge of blood, by the introduction of a reed of proper size, for some distance into the canal, and, when the case is very violent, a cord is passed along the urethra, and carried through the perineum. The two ends are then occasionally pulled to and fro, inducing great pain, and a copious hæmorrhage, with much swelling and inflammation of the penis. Two cures of confirmed tetanus are related by a gentleman of the name of Mariner to Professor Chapman of Pennsylvania, as having been performed by this strange and unpromising practice. The mode may suggest a principle capable of improvement.

ROYAL DENTAL HOSPITAL.—At the London School of Dental Surgery in connexion with this hospital a series of post-graduate lectures will be given during the months of October, November, and December, on Mondays, at 5.30. The following is the schedule. Oct. 21st and 28th: Recent Views on Immunity in Relation to Dental Disease, J. H. Mummery. Nov. 4th and 11th: the Retention of Dentures in Difficult Cases, E. Lloyd-Williams; Nov. 18th: the Movements of the Mandible, their Relation to the Production and Treatment of Abnormal Articulation of the Teeth and to the Articulation of Artificial Dentures, W. H. Dolamore; Nov. 25th: the Treatment of Superior Protrusion, J. F. Colyer. Dec. 2nd and 9th: the Etiology of Palatal Deformities, J. G. Turner. The fee for the course is £2 2*s*., but past and present students of the hospital and internal students of the University of London will be admitted free. Further particulars can be obtained on application to Mr. J. F. Colyer, the dean of the school at the hospital.

Public Health and Poor Law.

LOCAL GOVERNMENT BOARD.

REPORTS OF MEDICAL OFFICERS OF HEALTH.

The City of Cardiff.—Dr. Edward Walford embodies in his annual report an account of the sanitary condition of the 37 elementary schools in this city. Such schools together provide accommodation for 34,443 scholars and the sanitary condition under which the children are housed, embodying, as it does, questions relative to the admission of adequate light and fresh air as well as freedom from unwholesome conditions generally, is obviously a matter of supreme importance from a civic and a national standpoint. The inspection of these schools was commenced in 1905 and the action which has been subsequently taken in consequence of that inspection has resulted in great improvements being carried out. So satisfactory, indeed, were these results that a weekly inspection is now made by the medical officer of health and a report thereon presented monthly to the corporation. During 1906, 1482 scholars were excluded from school in connexion with infectious diseases, but no schools were closed. Dr. Walford is apparently in favour of the exclusion from school attendance of very young children and he thinks that by their exclusion some of the overcrowding which occasionally occurs in the class-rooms of the older children might be avoided. He recognises, however, the fact that in the poorest districts of the town the children are under worse conditions at home than they would be at school. Apparently, the education committee of the Cardiff corporation does not propose at present to undertake the medical inspection of scholars, although Dr. Walford draws attention to the necessity for investigation as regards the special senses, the condition of the throat and air passages, of the glands, and of mental capacity. In our view the organisation of such medical inspection should be carried out by medical officers of health, but it is clear that in the circumstances which obtain in populous places the medical officer of health would have neither the time nor the special knowledge for the actual work of inspection. Such inspectorial work might well be divided amongst the local medical practitioners, each officer working under a definitely arranged scheme making for uniformity of methods and classification in the several schools. Voluntary notification of pulmonary tuberculosis has been in operation in Cardiff since 1901, and in 1903 a woman inspector was appointed to visit all the cases notified and to report to the medical officer of health upon a printed form. Dr. Walford speaks in favourable terms of the work, as only such cases are notified as in the opinion of the attending practitioner are likely to benefit by the visitor of the sanitary authority. During 1906 there were 141 notifications of pulmonary tuberculosis and the disinfection of premises and articles was carried out by the sanitary authority in 128 instances. There were 222 deaths from pulmonary tuberculosis during the year. The infantile mortality in Cardiff during 1906 was 154 per 1000 registered births, the rates in the several wards having ranged from 86 to 189. While the general death-rate during the last 50 years has fallen from 22 6 to 15·2 per 1000 the infantile mortality shows but a slight decrease. But even this slight fall is encouraging as compared with the conditions obtaining in our urban districts generally. As Dr. Walford observes, the infantile mortality in this country compares unfavourably with that obtaining in Scotland and Ireland as also with that in Denmark, Norway, and Sweden. The evidence, in fact, suggests that the segregation of the population in large towns, especially manufacturing towns, is a very prejudicial influence as regards infantile mortality, conducing as it does to the diminution of breast-feeding and the employment of condensed milk and other foods.

The City of Westminster.—Dr. F. J. Allan furnishes in his current report a good illustration of the now well-known manner by means of which unrecognised cases of infectious diseases are responsible for the spread of such diseases. An outbreak of diphtheria occurred in a certain school in Westminster and the circumstances attending the outbreak suggested that the retention of infection in the throats of children otherwise just recovered from an attack may have been responsible for re-introducing fresh infection into the school and it also appeared from the distribution of the cases in two classes in the girls' department that proximity in the matter of seating may have been a determining factor in the spread of the disease as it was found that 13 out of 17 children attacked sat next to one another in class. As, however, there were only 29 girls in one class and 22 in the other, it is clear that on the basis of probability there must have been some infected children sitting near to one another. However, this proximity has been observed in other school outbreaks and there is probably ground for the opinion expressed by Dr. Allan. In order to assist in reducing the infantile mortality obtaining in this district the City of Westminster Health Society has arranged with certain general and lying-in hospitals in Westminster by which it is supplied from time to time with lists of impending maternity cases, and the health visitors are by this means enabled to visit the potential mother prior to confinement. Subsequently to confinement a monthly visit is paid during the first three months and afterwards quarterly. Dr. Allan quotes from the report of the health visitors which was drawn up after 400 cases had been visited. It is stated that out of 400 births 120 of the mothers had some occupation which necessitated the premature weaning of the *offspring*, and the following table purports to put the case statistically and to show the advantage *quâ* survival of being born of a non-working mother.

	Death-rate per cent.	Delicate infants per cent.
Working	9·1	25
Non-working	7·5	8·2

Among 282 breast-fed babies there were 18 deaths as against 14 deaths among 100 bottle-fed infants. As regards the health of the mothers themselves it was found that 60 suffered more or less from ill-health or general debility, a circumstance for which the strain of pregnancy and lactation was largely responsible. Drink or poverty was not frequently assigned as the cause of maternal ill-health. Nor did insufficient food during pregnancy appear to have promoted the observed condition. In the opinion of the visitors, ignorance, lack of cleanliness, and irregularity of feeding and of habits were the principal causes of infantile ill-health and death. In this connexion it may be mentioned that an infants' hospital has been established in Vincent-square, Westminster, its object being to carry out the study and treatment of infantile malnutrition and to afford medical practitioners and medical students an opportunity for detailed study of the factors governing infantile nutrition. Certainly, this hospital, if it carries out its programme, should do some useful work. Pulmonary tuberculosis is notifiable in a voluntary sense in Westminster, and Dr. Allan furnishes some instances where infection may have been contracted from a relative. Having regard, however, to the recent report of the Royal Commission on Tuberculosis, from which Dr. Allan quotes, it does not follow that a tuberculous relative was in actual fact the source of a child's infection; tuberculous milk of bovine source may very well have been the cause of both cases, and the interval between the two attacks an illustration of latency. During 1906 there were 76 notifications of pulmonary tuberculosis received.

Borough of Portsmouth.—At the beginning of 1906 the water supplied to Portsmouth by the water company evinced considerable cloudiness, indicating apparently that in times of heavy rain the water, which is, it seems, derived from springs, carries with it considerable material in suspension. The precise source of this opacity is not dealt with in the report before us, but the presence of vegetable matter is clearly an indication of the desirability of filtration, more especially as the springs are, we believe, not far distant from the town of Havant. An Act has, therefore, been passed which enacts *inter alia* that the company shall forthwith commence filtration works. The filtration clause is not to apply to water "drawn from borings or wells or adits driven therefrom," a proviso which seems to suggest that some of the cloudiness which has been observed in the water on several occasions may be due to surface washings or, at any rate, to water from the superficial strata Otherwise it is difficult to understand the *exemption* referred to. Possibly, however, the chalk hereabouts is so well covered with impermeable strata that if the upper portion of a well is properly protected from surface pollution the risk of specific contamination is regarded as negligible. In any circumstances the medical officer of health is to be congratulated on having, after some years of fighting, succeeded in providing for filtration.

VITAL STATISTICS.

HEALTH OF ENGLISH TOWNS.

IN 76 of the largest English towns 8753 births and 3915 deaths were registered during the week ending June 22nd. The annual rate of mortality, which had steadily declined from 17·9 to 13·1 per 1000 in the previous 11 weeks, further fell to 12·7 in the week under notice. During the first 12 weeks of the current quarter the death-rate has averaged 15·3 per 1000, the rate in London during the same period being 14·8. The lowest annual death-rates in the 76 towns during the week were 5·7 in Croydon, 7·0 in Hastings, 7·5 in Hornsey, and 7·6 in East Ham and in Kings Norton; the highest rates were 18·5 in Grimsby, 20·5 in Middlesbrough, 20·6 in Oldham, 20·9 in Huddersfield, and 24·1 in Wigan. The 3915 deaths in the 76 towns showed a further decrease of 111 from the numbers in recent weeks, and included 365 which were referred to the principal epidemic diseases, against numbers decreasing from 510 to 430 in the five preceding weeks; of these, 139 resulted from measles, 104 from whooping-cough, 53 from diarrhœa, 32 from scarlet fever, 27 from diphtheria, and 10 from "fever" (principally enteric), but not any from small-pox. The deaths from these principal epidemic diseases were equal to an annual rate of 1·2 per 1000, the rate from the same diseases in London being 1·3. No death from any of these epidemic diseases was registered last week in Southampton, Birkenhead, Stockport, Hornsey, or in 12 other of the 76 towns; the annual death-rates therefrom, however, ranged upwards to 2·5 in Derby and in Rotherham, 4·8 in Bolton, 5·9 in Wigan, and 6·1 in Middlesbrough. The fatal cases of measles, which had declined from 214 to 172 in the five preceding weeks, further decreased to 139 in the week under notice, and caused death-rates ranging upwards to 2·5 in Derby, 2·9 in Bolton, 4·1 in Middlesbrough, and 4·7 in Wigan. The deaths from whooping-cough, which had been 130 and 124 in the two previous weeks, further fell to 104 last week; the highest death-rates from this disease were 1·1 in St. Helens, 1·2 in Wigan, and 1·4 in Bolton. The fatal cases of diarrhœa, which had been 47, 49, and 50 in the three preceding weeks, increased to 53 in the week under notice, but the mortality was not excessive in any of the towns. The 32 deaths from scarlet fever showed a decline from the number in the previous week, and included 10 in London, three in Liverpool, three in Manchester, two in Leeds, and two in Newport (Mon.), the annual rate in the last-named town being 1·4 per 1000. The fatal cases of diphtheria, which had been 48 and 36 in the two preceding weeks, further declined to 27 in the week under notice; 10 of the deaths occurred in London, four in Hull, two in Portsmouth, and two in Middlesbrough. Of the 10 deaths from "fever," two were registered in Liverpool, two in Leeds, and one in each of six other towns. The number of scarlet fever cases in the Metropolitan Asylums Hospitals and the London Fever Hospital, which had increased from 2658 to 2936 in the six preceding weeks, had further risen to 2986 at the end of last week; 414 new cases were admitted during the week, against 437, 368, and 389 in the three preceding weeks. The deaths in London referred to pneumonia and other diseases of the respiratory organs, which had continuously decreased from 412 to 149 in the preceding 11 weeks, rose again to 156 in the week under notice, and were slightly above the corrected average number in the corresponding period of the five previous years. The causes of 33, or 0 8 per cent., of the deaths registered in the 76 towns during the week were not certified, either by a registered medical practitioner or by a coroner. All the causes of death were duly certified in Leeds, Bristol, West Ham, Bradford, and in 53 other towns; the proportion of uncertified deaths, however, showed a marked excess in Birmingham, Sheffield, and Bootle.

HEALTH OF SCOTCH TOWNS.

The annual rate of mortality in eight of the principal Scotch towns, which had been equal to 19·0 and 17·2 per 1000 in the two preceding weeks, was 17 3 per 1000 in the week ending June 22nd, and was 4 6 in excess of the rate during the same period in the 76 English towns. The rates in the eight Scotch towns ranged from 10·5 in Perth and 13·2 in Greenock to 18·1 in Leith

Dundee. The 600 deaths in the eight towns showed an increase of one over the number in the previous week, and included 84 which were referred to the principal epidemic diseases, against 109 and 83 in the two preceding weeks. These 84 deaths were equal to an annual rate of 2·4 per 1000, which exceeded by 1·2 per 1000 the rate from the same diseases in the 76 English towns; they included 37 which were referred to whooping-cough, 23 to diarrhœa, 14 to "fever," eight to measles, and two to diphtheria, but not any to small-pox or to scarlet fever. The fatal cases of measles, which had been 57 and 43 in the two previous weeks, further declined last week to 37, of which 19 occurred in Glasgow, five in Aberdeen, four in Edinburgh, four in Dundee, and three in Paisley. The 23 deaths from diarrhœa exceeded by 15 the number in the preceding week, and included 12 in Glasgow, five in Dundee, three in Edinburgh, and two in Leith. The deaths referred to "fever," which had been 26 and 24 in the two preceding weeks, further fell to 14 in the week under notice; 12 of these deaths were from cerebro-spinal meningitis, of which five were registered in Glasgow, five in Edinburgh, and one each in Paisley and Leith. The eight fatal cases of measles were three in excess of the number in the preceding week, and included four in Glasgow and two in Edinburgh. The deaths in the eight towns referred to diseases of the respiratory organs, including pneumonia, which had been 106 and 91 in the two previous weeks, further decreased to 86 last week, but were 17 above the number in the corresponding period of last year. The causes of 24, or 4 per cent., of the deaths registered during the week were not certified or not stated; the proportion of uncertified deaths in the 76 English towns during the same week did not exceed 0·8 per cent.

HEALTH OF DUBLIN.

The annual death-rate in Dublin, which had been equal to 23·1, 23·9, and 24·3 per 1000 in the three preceding weeks, declined again to 20·8 per 1000 in the week ending June 22nd. During the past 12 weeks the death-rate has averaged 25·9 per 1000, the rates in the same period being 14·8 in London and 17·4 in Edinburgh. The 156 deaths of Dublin residents registered during the week under notice were 26 fewer than the number in the preceding week, and included 19 which were referred to the principal epidemic diseases, against 13, 11, and 12 in the three preceding weeks; of these, nine resulted from measles, five from whooping-cough, two from diarrhœa, and one each from scarlet fever, from diphtheria, and from "fever." These 19 deaths were equal to an annual rate of 2·5 per 1000, the death-rates during the same period from the principal epidemic diseases being 1·3 in London and 1·5 in Edinburgh. The fatal cases of measles, which had been six and three in the two previous weeks, rose to nine in the week under notice, while the deaths from whooping-cough declined to five, having been successively eight, four, and eight in the three preceding weeks. The 156 deaths from all causes in Dublin last week included 26 of children under one year of age and 42 of persons aged upwards of 60 years; the deaths both of infants and of elderly persons were slightly below the respective numbers in the previous week. One death from violence and two inquest cases were registered; and 63, or more than 40 per cent., of the deaths occurred in public institutions. The causes of three, or 2 per cent., of the deaths in Dublin were not certified; in London only one uncertified death was registered, while in Edinburgh the percentage was 3·9. The 131 deaths registered in Belfast during the week under notice included 20 which were referred to cerebro-spinal fever or cerebro-spinal meningitis.

THE SERVICES.

ROYAL NAVY MEDICAL SERVICE.

THE following appointments are notified:—Inspector-General: J. Porter, C.B., to Royal Naval Hospital, Haslar. Fleet Surgeons: J. F. Hall to the *President*, additional, temporary, for London Recruiting Headquarters; and R. O. Munday to the *Formidable*. Staff Surgeons: M. O. Langford to the *Aboukir*; N. Ireland-Smith to the *Leander*; G. R. MacMahon to the *Blake*; and E. S. Miller to the *President*, for three months' hospital course at West London Hospital. Surgeons: H. Hunt to the *Blake*; J. J. H. Rooney to the *Leander*; and F. E. Anley to the *Victory*, additional, for Portsmouth Dockyard.

ROYAL ARMY MEDICAL CORPS.

Major Alexander Y. Reily retires on retired pay (dated June 22nd, 1907).

INDIAN MEDICAL SERVICE.

The King has approved of the following promotions among officers of the Indian Medical Service:—To be Surgeon-General: Colonel Henry Hamilton, C.B., V.H.S. (dated March 25th, 1907). To be Colonel: Lieutenant-Colonel Douglas ffrench-Mullen (dated March 25th, 1907). Majors to be Lieutenant-Colonels (dated March 31st, 1907): Charles Hardwick Louw Meyer, William Henry Wilson Elliot, D.S.O., Letterstedt Frederick Childe, William Ronaldson Clark, George Frederick William Braide, Robert John Marks, Charles Edward Sunder, Malcolm Albert Ker, Herbert Herbert, Thomas David Collis Barry, Andrew Buchanan, Lewis Gordon Fischer, William Vost, John Garvie, Clarence Edwin Lloyd Gilbert, Gerard Beatty Irvine, Frederick James Crawford, Robert Robertson. To be Lieutenant: Frank Phillips Wernicke (dated Feb. 1st, 1906).

The King has approved of the retirement of the undermentioned officer—Major Charles Louis Williams (dated March 19th, 1907).

ROYAL ARMY MEDICAL CORPS (VOLUNTEERS).

South Yorkshire Bearer Company: Lieutenant G. H. L. Hammerton to be Captain (dated April 10th, 1907).

VOLUNTEERS CORPS.

Royal Garrison Artillery (Volunteers): 1st Forfarshire: Lloyd Turton Price to be Surgeon-Lieutenant (dated May 22nd, 1907). 1st Renfrew and Dumbarton: Francis William Squair to be Surgeon-Lieutenant (dated May 17th, 1907).

Royal Engineers (Volunteers): 1st (Sheffield) Yorkshire (West Riding): Surgeon-Lieutenant A. C. Turner to be Surgeon-Captain (dated May 7th, 1907).

Correspondence.

"Audi alteram partem."

INSURANCE AGAINST SICKNESS.

To the Editors of THE LANCET.

SIRS,—The Compensation Act, 1906, has given new life to a very important branch of business—that of insurance. Employers are under an obligation to the insurance offices for mitigating the terrors of that Act, and so, too, are their employees. It is obvious that the first tendency of such legislation is to dispose employers to reduce the number of those whom they employ and to employ younger and more nimble servants rather than those who are otherwise. The insurance offices serve an admirable purpose in counteracting this tendency and enabling employers to take a more favourable view of legislation that without seriously hurting them tends immensely to diminish the many hardships of the working-classes when overtaken by accident in the course of their employment.

It is gratifying to find that the insurance offices, apparently stimulated by the Compensation Act, have formulated proposals for insurance by employers against sickness in their employees not having any legal claim on them for such aid. This is of special interest and value in the case of household servants. The acceptance of such proposals, with or without coöperation of servants, would be greatly to the advantage of this class when overtaken by serious ailments or disease. Its generous adoption by masters or mistresses would probably do more than anything else to mitigate the "servant question" that so worries ladies. But—and this is one of my principal objects in asking the hospitality of your columns—it is necessary to point out that the present list of diseases against which the offices offer insurance is very defective and does not include those diseases in servants which are the most anxious and troublesome. I would name three which are conspicuous by their absence from any list which I have seen and which are of common occurrence among domestic servants—ulcer of the stomach, appendicitis, and influenza. There is nothing which servants appreciate more than a little consideration in times of sickness and the addition of these *diseases* to the list will, I am sure, be a great boon to them and be greatly appreciated by them. I am not arguing for legislation making employers liable for sickness as well as accident in domestic servants. There is much to be said against such legislation. But I am arguing in favour of insurance against such diseases on reasonable terms being made possible by the insurance offices, believing that there are thousands of masters and mistresses who would generously use such facilities and that such generosity would be greatly useful in improving the sympathy and relations generally between them.

But I have one more object in writing this letter, and that is to urge the use of the insurance principle generally as against sickness in all its forms. It is surprising how little attention has been given to this element of risk in society. But it is very obvious and of late years has become specially so for a reason I shall immediately mention. The days are, I hope, come when a better account can be given of the best treatment of rheumatic fever than that given by Dr. Warren—"six weeks," but even so the element of sickness in the life either of one's family or of servants is too real to be left out of account. And one change in our profession has given special emphasis to this fact. I mean the development of the use of surgery since the discovery of antiseptics. Surgery meets us now at every point, generally beneficially and sometimes with miraculous results. But it is proportionately costly. I have had several patients in the last two or three years whose surgical fees have amounted to well over one hundred pounds. Medicine proper is more merciful in her charges, especially as represented by the modest, and often inadequate, fees of the general practitioner. It is no use debating whether the insurance offices or private patients are most to blame for such a defect in our insurance against obvious risks. But it is one which should be faced and we may look to the insurance offices to solve the problem in this curious time of wealth and impecuniosity. In doing so they will not only increase their own business and prosperity but will advance the solution of social problems without injury to the medical profession.

I am, Sirs, yours faithfully,

Highbury-place, N., June 24th, 1907. JAMES GREY GLOVER.

METROPOLITAN STREET AMBULANCE ASSOCIATION.

To the Editors of THE LANCET.

SIRS,—As the inquiry relative to ambulances now proceeding before the Home Secretary's committee presents an exceptional opportunity to the medical profession of London to put forward its views on the subject referred to, the above association desires to point out and emphasise the great importance of the inquiry and the responsibility it carries with it. The scope of the inquiry is thus officially described: "To inquire as to the provision made for dealing with cases of accident and sudden illness in the streets and public places within the metropolis and to report whether any, and if so what, improvements in ambulance provisions are necessary or desirable and how they could be best effected with due regard to efficiency and economy."

The nature of this inquiry relative to public safety is such as to bring it specially within the scope of the medical profession as being the authority most competent to judge as to the efficiency or otherwise of present methods or any other that may be proposed as a substitute. It should be remembered that many years may elapse before opportunity is again afforded for promoting action or legislation in reference to this most important subject. The Metropolitan Street Ambulance Association, as largely representing the medical profession practising in the metropolis—which number might be added to indefinitely—and also including the Metropolitan Branch of the British Medical Association, desires to ask the cordial coöperation of the profession generally to matters directly affecting the safety and protection of all persons who use the streets of London.

The association therefore desires to point out in the interests of all concerned: (1) that the present position for dealing with such accidents and casualties in the streets is admitted to be inadequate and obsolete and that an unnecessary amount of mortality and physical suffering is thereby permitted to continue; (2) that though the better organisation of existing ambulance provision may to some extent improve matters a more extended system of first aid by the police or others who may undertake this duty, as well as improvements in signalling and in appliances and forms of ambulance are absolutely and urgently needed; (3) that no service for London can be regarded as efficient that does not include a proportion of rapid transit ambulances, motor or horse, capable of communicating immediately with accidents when authoritatively requisitioned by telephone or otherwise and containing, if required, necessaries for first aid attendance; in fact, in special circumstances and urgency reversing the order of things and *bringing the hospital, so to speak, to the patient* in the street.

Further information relative to the action which is being taken by the Metropolitan Street Ambulance Association to promote a more efficient service for the many thousand accidents occurring annually to men, women, and children in the streets of London may be obtained from the honorary secretary of the association, Dr. Arthur W. James, 69, Gloucester-terrace, Hyde Park, W.

I am, Sirs, yours faithfully,

REGINALD HARRISON,
President, Metropolitan Street Ambulance Association.

Lower Berkeley-street, W., June 24th, 1907.

NOTES OF A CASE IN WHICH GLYCOSURIA, DEPENDING UPON CHOLECYSTITIS AND CHOLANGITIS, DISAPPEARED AFTER DRAINAGE OF THE BILE-DUCTS.

To the Editors of THE LANCET.

SIRS,—The notes of a case by Mr. C. W. Mansell Moullin reported in your issue of June 15th are of great practical importance and of especial interest to me in that it adds one more fact to those I have already advanced—that infection of the bile channels is frequently accompanied by infection of the pancreatic ducts leading to catarrhal pancreatitis which may pass on to interstitial pancreatitis and in some cases even to interacinar pancreatitis when glycosuria may be expected to supervene. In this case it seems to me that the title of the paper might have been more fittingly expressed as "Notes of a Case in which Glycosuria depending on Catarrhal Pancreatitis and associated with Common-duct Cholelithiasis disappeared after Removal of Gall-stones from the Common Duct and Drainage of the Infected Bile-ducts." My writings on this subject have evidently escaped Mr. Mansell Moullin's notice or he would not have written "Hitherto glycosuria, when occurring in association with cholecystitis and cholangitis, has been regarded as a bar to operation. As a matter of fact, it is one of the strongest arguments in favour of it. Thorough drainage not only prevents further injury being inflicted upon the gland by the septic organisms that have invaded it, but, as in the above case, restores the gland to the condition in which it was before the septic invasion took place. So far as I am aware, this is the first case in which a result of this kind has been recorded."

If Mr. Mansell Moullin will refer to the address that I delivered before the Royal Medical Society of Edinburgh on the Clinical and Pathological Importance of Chronic Pancreatitis, and which was published in the *Edinburgh Medical Journal* for December, 1905, he will find the following paragraph: "I do not think that a moderate degree of glycosuria need be a bar to operation, as this may arrest the progress of the disease"; but even before this, in my Address in Surgery before the Canadian Medical Association in August, 1904, which was published in the *Montreal Medical Journal* for November, 1904, will be found the following paragraph after the reports of some cases: "This case raises the question whether operation ought to be declined because of the presence of a small amount of sugar in the urine. In future should the patient's condition be fair I shall feel inclined to recommend operation in order to remove the obstruction, and by drainage to arrest the pathological process going on in the pancreas."

The subject of the relations of pancreatic catarrh and chronic pancreatitis to glycosuria is a very large one and is not so simple as at first sight it might appear. In a work on the pancreas, now in the press and to be issued shortly, my colleague, Dr. P. J. Cammidge, and I have dealt very fully with the subject of pancreatic diabetes, and my experience of operations in four cases of glycosuria is given. The following abstract from this work may be of interest to Mr. Mansell Moullin and others who may have read his paper :—

> *Chronic interstitial* pancreatitis *has been frequently observed* in association with diabetes, but in the majority *of cases* where interstitial changes in the pancreas arise from obstruction of the ducts by gall-stones *or from other causes, glycosuria* is not met with as a symptom. In 65 consecutive cases where biliary calculi were found in the common duct at operation and the pancreas was enlarged and hard, we have only detected sugar in the urine *of four (6 per cent.). In three of* these the amount was under 0·2 per cent., and in the fourth 0·4 per cent. was present. After operation the sugar disappeared from the urine in all but the last one, in which it slowly increased in amount, the patient dying from diabetic coma ten months subsequently. Since the interstitial changes *arising from* the presence of gall-stones in the common duct principally affect the head of the gland in the first instance, and the results of experiments upon animals have shown that even a small portion of healthy pancreatic *tissue will prevent the onset of* diabetes, or at least delay the appearance of the symptoms so long as it remains undestroyed by fibrotic changes, the comparative rarity of glycosuria in these cases is not difficult to explain. When, however, a great part of the parenchyma has been destroyed or is functionally impaired by the progressive changes consequent on repeated or long-continued irritation, either from gall-stones or an unrelieved duodenal catarrh, sugar will make its appearance in the urine, first as an alimentary glycosuria; *and later as a permanent diabetes.*

I am, Sirs, yours faithfully,

Park Crescent, W., June 17th, 1907. A. W. MAYO ROBSON.

VAGAL ATTACKS.

To the Editors of THE LANCET.

SIRS,—In his lecture on Vagal and Vaso-vagal Attacks in your issue of June 8th Sir W. R. Gowers has defined for us certain types of seizures hitherto included in the general category of hysteria. They belong to a class of disorders in which the causes are complex and the varieties manifold, scarcely any two cases being alike in the sense that two cases of scarlet fever or of tuberculosis are alike. It is therefore especially helpful to have clinical pictures drawn of these types, so that cases can be grouped under one or other or in a mixed form under two such types. Sir W. Gowers performed a like service in his recent lecture on "Faints and Fainting,"[1] in which the relations of syncope and epilepsy were dealt with. Many of your readers will recognise cases of their own in the description given by our author of vagal attacks. Let me mention one recently under my observation. The patient is a married lady of about 35 years of age, whose father and father's sister have had mental trouble. She has herself been liable to depression of spirits, especially so after her first confinement. Having lived in a tropical climate she has suffered often from malaria and rheumatism, but not severely. Two and a half years ago she began to show signs of mental disturbance in alteration of disposition and temper, and these signs were much increased on the occurrence of pregnancy shortly afterwards. She became melancholic and physically weak, so that on consultation it was deemed necessary to terminate the gestation. By this she was much relieved, but a chronic mental state came on characterised by inability to make decisions, consequent uncertainty of mind over every step, constant regrets, and lessened power of attention. This condition lasted for about a year, after which it improved and she is now nearly recovered. During this period of mental disturbance she was liable to the frequent occurrence of "*storms*," so called by her husband, to whom I am indebted for a very intelligent description of her symptoms. These seizures began with a feeling of præcordial constriction and a sense of impending evil or a "*guilty feeling*," *as* if she had done something wrong. She wept and bemoaned herself. There was often occipital headache, fluttering or a feeling of turning over at the heart, and difficulty of breathing, sometimes great; also diarrhœa. When the attacks were severe the extremities became cold, even intensely so, the *fingers* and *toes* were blue and numb or tingling. Rigidity of the fingers was sometimes present, the joints of each finger being flexed in varying degrees "so as to render the hand most odd-looking." *Consciousness* seemed to be impaired, *as she gave no reply to* questions. These attacks *still* occur but in a slighter form, apparently excited by extra fatigue or the catamenial period. The seizure belongs evidently to Sir W. Gowers's vagal class, with a mixture of vaso-motor influence especially when the attack is severe.

I should like to suggest the value of bath treatment in cases of this kind. Two ends may be attained by it. In the first place there is the sedative effect upon the nerve centres of massive sensations of gentle warmth from the periphery, obtained by the use of subthermal baths, aided in some cases by the addition of fragrant pine extract to the water of the bath. Secondly, in cases in which vaso-motor spasm is present the use of the warm bath, which may be taken nightly, dilates the vessels of the surface and equalises the circulation. In a case of labyrinthine disorder, aggravated by vaso-motor spasm, I found the effect most soothing, and the tinnitus constantly present was always less loud whilst the patient was lying in the bath.

I am Sirs, yours faithfully,

Weymouth-street, W., June 15th, 1907. R. HINGSTON FOX.

To the Editors of THE LANCET.

SIRS,—Sir William Gowers has recently written some exceedingly suggestive and helpful articles,[1] among which the lecture appearing in your issue of June 8th, entitled as above, is by no means the least interesting and instructive. When I had read it, however, I wondered why the attacks therein described should be called "vagal," and on re-reading it my wonder under this head was not diminished. Sir William Gowers has given us many good words (e.g., "knee-jerk" and "fibrositis") and has so often shown that he is not only a *literary but also an etymological purist* that one, at least, of his admirers is rather shocked that he should lend the weight of his authority to what may be described as a misnomer which is more than usually calculated to obscure the truth.

It is not my purpose *to venture* any *suggestions* as to how these attacks originate, but I submit that there can be no reasonable doubt that the *symptoms* are due, not partly, as Sir William Gowers suggests, but altogether to vaso-motor spasm, a process in which, so far as is known, the vagus takes no part. The vagal *symptoms*, as opposed to the vaso-vagal, are described in the lecture as sensations referred to the stomach, the respiratory system, and the heart. They consist in a sense of oppression at the epigastrium which is never accompanied by vomiting, a sense of *respiratory* distress *often amounting to orthopnœa*, and cardiac disturbance, such as præcordial discomfort amounting in some cases to acute pain, with a sensation of sudden stoppage of the heart, followed by rapid action. During the attack there is generally the "anginal" sense of alarm and fear of impending death.

If the existence of a vaso-motor spasm be granted, it does not seem necessary to invoke the aid of the pneumogastric to explain the above phenomena. With constricted arterioles would come overfulness of the *venous system*. This would *account for* the epigastric discomfort by sudden distension of the right ventricle; by an obvious process it would also account for the respiratory distress. The increase of tension in the larger arteries would react upon the heart so as to overfill the left ventricle and thus create the feeling of sudden stoppage. It would also evoke the pain and the anginal sense of impending death. Sir William Gowers would add to the many obligations under which he has already placed *the profession* if he would *stand* godfather to these attacks and supply us with a name which does not imply a doubtful theory of causation. And, after all, are they—these seizures—so very *different* from those described by Nothnagel[2] *as angina pectoris* vaso-motoria and by Huchard[3] as pseudo-angine névrosique?

I am, Sirs, yours faithfully,

London, W., June 18th, 1907. LEONARD WILLIAMS.

To the Editors of THE LANCET.

SIRS,—Dr. Leonard Williams has kindly allowed me to see his letter (printed above). The causal significance he finds in the term "vagal" was not in my mind when I *adopted* it. The word was chosen only *as convenient* and descriptive, at any rate as conveying the fact that the symptoms are chiefly within the functions of the pneumogastric. Thus used, no advance in our knowledge can make it inaccurate. It does not seem to me to imply the hypothesis Dr. Williams has found in it. The possible vaso-motor origin of all the sensory symptoms of the attacks was not referred to, partly because it is doubtful whether all can be thus explained (or only thus), but chiefly because my object was to contribute to our knowledge of the symptoms and relations of these attacks and to avoid hypothetical explanations. These I gladly leave to others, and their value will be great if they stimulate precision of observation on the part of those under whose notice such attacks may come.

[3] Maladies du Cœur, vol. ii., p. 200.

The symptoms met with in these attacks have, no doubt, often been mentioned. The "vaso-motor angina" described by Sir Douglas Powell is clearly similar in essential nature. I regret if I seemed to suggest an originality I did not intend to claim. I am, Sirs, yours faithfully,

June 25th, 1907. WILLIAM R. GOWERS.

GARDEN SUBURBS AND GARDEN CITIES.

To the Editors of THE LANCET.

SIRS,—I hope you will be kind enough to allow me to correct one or two points of detail in the most interesting and sympathetic article on Garden Suburbs and Garden Cities in THE LANCET of June 8th, which has only recently been brought to my notice. The writer states that the Hampstead Tenants Society has bought the Hampstead Garden Suburb, but, as a matter of fact, the Tenants Society is a subordinate society leasing land for cottage property from the Garden Suburb Trust, just as a similar society, the Garden City Tenants, does at Letchworth. Garden city and suburb companies do not as a rule build themselves but content themselves with owning and laying out the land, and therefore these societies, often called by their German name of "Societies of Public Utility," coöperate with them by building the smaller houses, or a number of them at least. The houses are built and owned by the society, tenants being encouraged to become members. The return to capital is limited, any surplus going to tenant members. The system permits and encourages the detailed development of the town-planning idea, as it enables groups of houses to be built in relation to each other, with a due proportion of open space and garden. The object of the society is to do the best it can for the tenants, not to make the greatest return to capital. It is the Hampstead Tenants, Ltd., which recently started building operations, when Mrs. Barnett kindly cut the first sod.

These societies, which are developing throughout the country, both in connexion with larger schemes, as at Hampstead, Letchworth, and Wolverhampton, and independently, as at Ealing, Oldham, and Sevenoaks, are united in the Co-partnership Tenants Housing Council, which is the propagandist association for this part of the movement. May I add that I was especially glad to know that your article laid emphasis on the importance of the agricultural belt at Letchworth? This is, to my mind, the essential point in any garden city scheme, as distinguished from a garden suburb. The price of land puts it beyond the scope of privately started garden suburbs, but is it too much to hope that town-planning, when it becomes general, will involve a *limit* and a carefully preserved agricultural belt beyond that limit? Are our town areas to be allowed to cover the country and run into each other indefinitely, so that the real country becomes more and more unapproachable? I would suggest that agricultural belts will be a necessity if we wish to preserve the health and vigour of our population.

I am, Sirs, yours faithfully,
SYBELLA GURNEY,
Hon. Sec., Co-partnership Tenants Housing Council.
Bloomsbury-square, W.C., June 22nd, 1907.

THE COUNCIL ELECTION AT THE ROYAL COLLEGE OF SURGEONS OF ENGLAND.

To the Editors of THE LANCET.

SIRS,—I have had several inquiries from Fellows of the College as to which of the candidates at this election are in favour of some reform in the direction of giving the Members reasonable representation. I have not been in communication with any of these gentlemen, and do not know their views, with the exception of *one*—Mr. W. Bruce Clarke—who has frequently spoken and written in favour of this reform. I have therefore advised my correspondents to vote for him, and would urge all other liberal-minded Fellows to do the same. I am, Sirs, yours faithfully,

W. G. DICKINSON,
Hon. Sec., Society of Members of the Royal College
June 24th, 1907. of Surgeons of England.

SOME PHYSIOLOGICAL EFFECTS OF HIGH-FREQUENCY CURRENTS IN DISEASE.

To the Editors of THE LANCET.

SIRS,—With reference to Dr. S. Sloan's interesting article which appeared in THE LANCET of June 8th, p. 1557, entitled "Some Physiological Effects of High-frequency Currents in Disease," it appears to me highly desirable that further particulars should be given respecting his apparatus, for without these it is impossible to conclude whether some of his deductions are correct and his conclusions valid in so far as the application of these high potential currents is concerned. It is all the more necessary that these particulars should be supplied in view of the queries he himself has raised, apart from his desire to have a scientific commission appointed to investigate the whole subject. It is more on the physical than the physiological aspects of *his* paper that I should like to comment, it being *self-evident* that the trustworthiness of the latter depends upon the accuracy of the former.

The following are the points upon which I would like to have a reply from Dr. Sloan: (1) What are the voltage and ampèrage taken from the mains or *source* of supply on the primary side of the apparatus? (2) What are the voltage and maximum ampèrage of the apparatus? (3) How is the external circuit connected to the apparatus? (4) Is it in series or parallel? (5) How is the earth circuit connected with the apparatus? (6) In what part of the external circuit is the earth connexion made?

I am, Sirs, yours faithfully,
J. CUNNINGHAM BOWIE, M.B. Glasg.
Cardiff, June 18th, 1907.

THE REDUCTION OF DISLOCATION OF THE THUMB.

To the Editors of THE LANCET.

SIRS,—I should like to draw attention to what I believe to be an improved method of reducing the usual dislocation of the thumb. A few days ago, having failed to reduce a dislocation of the thumb by the ordinary method as described by *Rose and Carless*, 1902 edition, and in view of the fact that they state that the tension of the flexor longus is one of the chief hindrances to reduction, I made a further attempt at reduction *with the wrist completely flexed* and I applied the two half hitches of bandage, with which I grasped the thumb to the first phalanx so as to allow *the second phalanx to flex* and so still further relax the flexor longus tendon. I then pressed the metacarpal bone firmly into the palm of the hand to relax the short flexor; having thus relaxed all the muscles that were opposing reduction I then made traction in the usual way, first backwards, and by the time I had got the thumb straight the dislocation was reduced. Of course, it may have been a pure coincidence and have nothing to do with the relaxation of the flexors and I am sending you this letter in the hope that others may test the value of the method. I am, Sirs, yours faithfully,

LESLIE B BURNETT.
Oxford East, Canterbury, New Zealand, May 7th, 1907.

NOTIFICATION OF BIRTHS BILL.

To the Editors of THE LANCET.

SIRS,—I venture to point out that an amendment in the report stage of this important Bill would be of threefold advantage. According to the present wording it is laid down that notification must be made to the medical officer of health for the district; the altered wording I would suggest is that "notification should be made to the local supervising authority under the Midwives Act in England and Wales, and in Scotland to the local sanitary authority under the Public Health (Scotland) Act, there being no local supervising authority in Scotland.

The advantages that would, in my opinion, be gained by this change are the following. 1. The county and county borough authorities, which in many cases have already done valuable public work in promoting the provisions of the Midwives Act (1902), would remain the responsible bodies, able and willing to deal with the valuable statistics, especially regarding cases of stillbirths, which will before long be available, after the passing of the Notification Act, and which are already enforced on the midwife. The duties of supervising authorities as to midwives would merely be extended, as they have in a large proportion of cases the existing needful machinery and can avail themselves of inspection and classification of figures in their reports. 2. Midwives should not be obliged to notify stillbirths to *two* authorities; this will be the case if the present wording be adhered to and much confusion must inevitably result. 3. The mother and infant, if the latter be living, should be kept calm and quiet in so far as this condition is possible in a poor home; such quiet is scarcely to be obtained if two different authorities, as may be the case in London, have power to visit after a birth is notified, within 36 hours, through their inspectors, in order to advise as to details of feeding, &c. This advice may be most necessary and useful, but there should be no clashing in the nature of the information given or by the authorities responsible for it. To be of practical service it should be clear, concise, and simple. Notification at 48 hours would probably be more easily enforced.

I beg to add that I write in my individual capacity and not in any way as undertaking to represent the views of the Central Midwives Board. I have long been interested in the whole subject of high maternal and infantile mortality. The Notification Bill attempts to deal with the latter part of this question, hence my desire for alteration in the wording of the same.—I am, Sirs, yours faithfully,

J. WILSON,
June 24th, 1907. Member of Central Midwives Board.

THE NEW VACCINATION ORDER.

To the Editors of THE LANCET.

SIRS,—I should like to say how fully I appreciate the able and exhaustive article by a Public Vaccinator which appeared in your columns last week. It is impossible to add anything to the trenchant remarks he made. The only point I can make is, what are the best steps to take to induce the various boards of guardians to grant us a reasonable fee for the services we are called upon to render? I cannot help feeling that in a question of such vital importance to many men the question of fees should have been laid before Parliament and that some opportunity should therefore have been given of hearing our own members' opinion. The very autocratic action of the President of the Local Government Board hardly seems in consonance with the democratic views he is supposed to have held. We as public vaccinators have had nothing to do with the construction of the Act of 1898; neither were we consulted with respect to the issue of the Local Government Board Order under that Act. But we imagine, and not without good reason, that the person responsible for the fixing of the *minimum* fee in the Order had good and sufficient reasons for saying to the boards of guardians that it should not be less than 5*s*. I can well understand the attitude taken up by many boards of guardians when they found that their expenses under the Act of 1898 amounted to practically *four* times the amount paid before that Act came into operation. In such circumstances was it not the bounden duty of the Local Government Board, believing as they were bound to do in the new ordinances, to say to the boards of guardians, "We will relieve you of the extra amount you have to pay as we consider that this is a matter of national importance and therefore we will call upon the Chancellor of the Exchequer to refund you the amount you have paid since the Act of 1898 was passed"? I am, Sirs, yours faithfully,

June 24th, 1907. ANOTHER PUBLIC VACCINATOR.

BEES' STINGS AND RHEUMATISM.

To the Editors of THE LANCET.

SIRS,—In answer to the question of Dr. E. W. Ainley-Walker in your last issue I can narrate an example of the belief that the stings of bees have a curative effect in rheumatism. Some eight years ago, when I was travelling, the mate of a cargo boat showed me an apparatus that he informed me had belonged to his father who had been cured of very severe and obstinate "rheumatism of the spine" by its use. It consisted of a metal piston working in a cylinder in which it could be withdrawn or released by means of a spring. On the "business end" of the piston were set concentric rings of needles projecting about one-eighth of an inch from the end of the piston; the instrument was used by applying it over the affected part and releasing the spring sharply; by this means the skin was scarified in the same sort of way as I believe is employed in some modern tattooing. In this process, however, the ink was replaced by a dark-brown and somewhat viscous solution that I was assured was prepared from the stings of bees. My informant's father had obtained it many years before from a German chemist and was said to have derived the greatest benefit from the use of this certainly heroic remedy. It was a condition of success that the fluid should be rubbed in very vigorously, and it was said to produce a smart inflammatory reaction, which is hardly surprising. My informant only had a little of the fluid left and he did not know whether it could still be obtained anywhere. His father apparently had it applied all down his spine and I imagined at the time that it was a case of osteo-arthritis and that the benefit was produced simply by counter-irritation. It is possible, however, that it may have had some *specific effect as the patient supposed.*

I am, Sirs, yours faithfully,

June 24th, 1907. TATTOO.

ULISSE ALDROVANDI: THE CELEBRATION OF THE THIRD CENTENARY OF HIS DEATH.

(FROM AN ITALIAN CORRESPONDENT.)

Bologna, June 14th.

TRUE to her best traditions, the "Mater Studiorum," the "Mother City of Universities," has this week been giving hospitable entertainment, intellectual and social, to the representatives of nature-study in Italy and abroad assembled to assist her in commemorating, 300 years after his death, the most versatile, the most accomplished, in some respects the most typical of her sons. THE LANCET[1] has already given in outline the main features of that sagacious, energetic, even romantic figure, and has now to report the commemoration (or shall I call it the "amende honorable"?) by which Bologna has brought him back to the world of to-day as one of the most enterprising and unwearied of those workers who, possessed of all the learning of the old civilisation, prepared the post-Renaissance generation for the construction of the new.

It is to the Senator Giovanni Capellini, professor of geology in the university, that we chiefly owe the commemoration of Ulisse Aldrovandi, as indeed we owed to him, in great measure, the most interesting academic demonstration of last century, the eighth centenary of the Bologna school on June 12th, 1888. Appropriately, therefore, on the same day of the same month the same professor opened the proceedings of the present week with a few words of welcome to his brother nature-students in Italy and from outside nationalities, describing the inception of the commemoration and dwelling on the reconstruction of the Museum Aldrovandinianum, in which Aldrovandi's marvellously rich and artistically prepared specimens of the vegetable and mineral kingdoms, with his beautiful drawings and engravings of the animal world, have at last been brought together, classified, and made available for the historian of inductive research. Concurrently with this reconstruction of the museum, Professor Capellini drew attention to the publication of the annals of the Bologna school, the first *fasciculi* of which have seen the light this week, and been distributed to the delegates, Italian and foreign—to wit, the "Chartularium Studii Bononiensis" and the "Studi e Memorie per la Storia dell' Università di Bologna." These documents the said delegates will carry home to their respective seats of learning, together with another gift from Professor Capellini and his committee, a bronze medal artistically struck in memory of the unveiling of the tablet to Aldrovandi, placed on the wall of the Archiginnasio side by side with that commemorating the octocentenary of 1888. Professor Capellini, on resuming his seat amid rounds of applause from the vast audience, called on Signor Janari, the pro-Syndic, to give Bologna's welcome to the delegates. This was done with the grace and happy effect of an accomplished member of the Italian Parliament, after which the turn came to Dr. Vittorio Puntoni, Rector of the University, professor of Greek, and well known to scholars for his edition of Herodotus. Speaking in the pure flowing Latinity of which he is a master, Professor Puntoni was easily understood even by the less "classical" of his auditors, as he dwelt on the many-sided culture of Aldrovandi, which showed itself not only in nature-study, but in archæology, in law, and in literature, down to the "elegant pastime" of Latin verse. Nature-study, continued Professor Puntoni, so far from militating against proficiency in other pursuits, is their best ally, as it is only under nature's *guidance* and *only* by studying, so to speak, before her mirror that the artist and the poet—nay, the votary of law and legislation—can reach that truth, that reality, which gives enduring value to their work. Borrowing the noble words addressed by Marcus Aurelius to nature—*ἐκ σοῦ πάντα, ἐν σοὶ πάντα, εἰς σὲ πάντα*—Professor Puntoni saw the secret of Aldrovandi's success in his loyalty to that motto and concluded his brief, telling harangue with a period quite impressive in its cadence which evoked general applause as he resumed his seat. Next to address the audience was the representative of the Government, Signor Sanarelli, who, speaking in name of the departments of education, agriculture, and commerce, acquitted himself with more than official competence, and then, in long series, came the delegates of the foreign schools. Professor Spiridione Brusina of the Accademia Scientifica of Zagabria (Croatia) led off, followed by M. Léon Pélissier, who holds the chair of history in the University of Montpellier. This "vero tipo del Francese meridionale," as an Italian described him, spoke admirably, dwelling on the magnetic influence of Aldrovandi, whose name, he said incidentally, was borne by a flower which he had classified, and concluding with an impassioned salutation to the Bologna school, to Italy, and to the Italian King. The applause that ensued was general, mainly from the serried ranks of students at the back of the hall who behaved well throughout, in spite of a few sporadic cries of "Viva la Francia Anticlericale!" Great Britain, Roumania, and the United States of America came next, the British schools (Oxford, Cambridge, Glasgow, and St. Andrews) being respectively represented by Mr. W. Ashburner, Professor A. C. Seward, Professor Ferguson, and Dr. J. P. Steele. By arrangement with Professor Capellini, where several seats of learning from the same nationality were *en évidence*, their spokesman was selected from one of their delegates; and so the task of addressing the audience on the part of Great Britain fell to the professor of chemistry in the University of Glasgow, Dr. John Ferguson, who made a brief, pointed, and highly-finished speech, which, though conveyed in English, went home to the audience with centripetal effect. Professor Wieland of New Haven (U.S.A.) spoke, also in English, and was cordially received, while Professor Schück of Upsala, who holds the chair of fine art, literature, and the history of æsthetics, delivered a glowing oration in Italian, which proved one of the most successful of the series. And so in a sort of academic "march-past" university after university, from all regions of Christendom, paid its tribute to the hero of the day, each spokesman, as he resumed his seat, handing to Professor Capellini the specially prepared address of his school, engrossed on vellum, and often a fine work of illuminative art. Conspicuous among these was the address of the University of Cambridge, conveyed by Professor Seward, F.R.S., Emmanuel College, and written, I believe, by the public orator, Professor J. E. Sandys. This fine specimen of what a fraternal greeting of one seat of learning to another ought to be was greatly admired when exposed with all the others to public view in the Museum Aldrovandinianum and may here be given *in extenso*.

---

Illustrissimae Litterarum et Artium
Universitati Bononiensi
S. P. D.
Universitas Cantabrigiensis.

Abhinc annos undeviginti viri doctissimi, Universitati vestrae [illegible] annos octingentos ab origine sua feliciter exactos libenter gratulati sumus. Hodie vero non minus libenter vobis [illegible] gratulamur, quod, una cum Universitatis vestrae die natali, etiam alumni vestri insignis, ULYSSIS ALDROVANDI, memoriam perpetuam estis celebraturi. Rerum autem naturae indagator ille indefessus, qui abhinc annos trecentos de vita decessit, olim, velut alter Ulixes, orbis terrarum regiones remotissimas peragravit, atque, operibus magnis eruditissime conscriptis, etiam Varronis Bononiensis nomen est adeptus. Ingenio pariter ad plurima versatili praeditus, primum, adhuc iuvenis, urbis Romae de statuis antiquis Italiae in lingua hodierna opus eximium condidit; postea, pictoribus et sculptoribus optimis aere suo conductis, animantium exemplis plurimis accuratissime delineandis et uberrime explicandis volumina ingentia, Romae antiquae in lingua universa conscripta, dedicavit. Non immerito igitur unus e poëtis vestris ab alumno vestro insigni laboriosissime descriptas miratur

> 'multiplices rerum formas, quas pontus et aether
> exhibet, et quidquid promit et abdit humus.'

Ille ergo, qui vobismet ipsis Museum suo labore per annos plurimos rerum naturae miraculis instructum legavit, orbi terrarum reliquit litterarum monumenta a se condita; reliquit rerum naturae studiosissimo cuique nominis memoriam in perpetuum colendam et conservandam. Viri autem tanti fama, quae patriae profecto gloria est, patriae tamen finibus nequaquam terminatur. Septentrionali quidem Europae in regione Carolus Linnaeus, cuius memoria in anno eodem celebratur, ALDROVANDI nomen inter antecessores suos honoris causa memoravit. Nos autem, eiusdem in honorem, ex insulis nostris ad occidentem solem spectantibus scientiae botanicae professorem nostrum eximium ad sacra vestra saecularia mittimus, qui nostrum omnium nomine et Italiam, tot studiorum nostrorum matrem, et Bononiam, inter tot doctrinae sedes antiquissimam, reverentia debita salutet. Valete.

Datum Cantabrigiae
Idibus Martiis
A. S. MCMVII°.

The discourse of the day—the "Éloge" of Aldrovandi—was next delivered by Dr. Emilio Costa, professor of Roman law in the University of Bologna—a masterly performance replete with interesting references to the history of the school, but to some extent handicapped, coming as it did at the close of a long series of speeches and addresses on an exceptionally warm day in June. Copies of Signor Costa's "Éloge" in a printed form were distributed to the foreign delegates as they left the hall and will doubtless be valued by them, as was the similar oration, similarly delivered, of the poet Carducci at the octo-centenary celebration of 1888.

The unveiling of the "Lapide Commemorativa" to Aldrovandi, in the quadrangle of the Archiginnasio, was the next "function," admirably performed by Professor Pietro Pavesi of the zoological chair in the University of Pavia, who dwelt luminously and glowingly on the relations between the "Mater Studiorum" and her daughter—in some respects "matre pulcrâ filia pulcrior"—of Lombardy.

On the following day (the 13th) the reconstructed Museum Aldrovandinianum was inaugurated in a fervid speech of Professor Capellini, who inveighed with just indignation against the compatriots who had allowed so much noble work as that of Aldrovandi to lie so long neglected, even when not wilfully dispersed, and in some cases irreparably lost. As it stands, however, the collection is a marvellous monument of sagacity, energy, and free-handed largess—the nature-student, as comprehensive and wide in his horizon as Aristotle, sacrificing everything, health, ease, worldly means, to the advancement of truth and to the inculcation of the Hippocratic principle that nature-study lies at the basis of human culture and has its culmination and crown in the healing art.

The excursions and the visits to the centres of scientific equipment in Bologna and its neighbourhood—especially the "Museo Indiano," due to the learning and liberality of the professor of Indo-Germanic philology, Count Francesco Lorenzo Pullé, whose travels in the East have so redounded to the advantage of science—occupied the rest of the day, and in the evening a grand banquet at the Hôtel Brun brought the commemoration to a brilliant and felicitous close.

ST. THOMAS'S HOSPITAL.—DISTRIBUTION OF PRIZES.—The prizes for the summer session 1906 and the winter session 1907 won by the students at this hospital were distributed on June 26th by Mr. H. Rider Haggard, J.P., in the Governors' Hall of the institution. For the session 1906-07 the entrance scholarship of £60 was awarded to Mr. W. M. Littlewood and the University scholarship of £50 to Mr. O. V. S. de Wesselow. The Bristowe medal was awarded to Mr. C. M. Page, the treasurer's gold medal to Mr. J. A. Clark, and the Sutton Sams Memorial prize by Mr. H. B. Whitehouse. In his address Mr. Rider Haggard said that the superstitions of the world which the students were going to face were almost as many as those of the Middle Ages. It was the work of the medical man to combat these. The medical man in all things should strive to earn the noble title of beloved physician.

THE RENEWAL OF THE SANDGATE SANATORIUMS SCANDAL.

(FROM OUR SPECIAL SANITARY COMMISSIONER.)

(Continued from p. 1606.)

IN spite of the compensation clause introduced by the House of Lords it was maintained by some of the persons concerned that there was still virtue remaining in the Sandgate Urban District Council Sanitary Powers Act of 1905. The former clerk to the council, Mr. L. J. Drake Brockman, notably, argued energetically in favour of enforcing this new law. But the opinion was spread that the law was only useful in so far that it would provide a pretext for litigation, which would only benefit the lawyers and experts concerned. It is thought by some persons that the council might have yielded to such protest but for the action of the medical officer of health and Mr. Brockman. These two gentlemen insisted that the law should be applied, and the council after some hesitation consented to draw up regulations and to send them for approval to the Local Government Board. Section 3 of the Act empowers the council to make regulations in regard to places called "hospitals for disease," which, for the purposes of this Act, are dwellings where persons suffering from tuberculosis are to live and to be treated. Such places must now be licensed, and before granting such licence the council is supposed to make regulations in regard to structure, drainage, ventilation, surrounding air space, number of patients to be admitted, administration, &c.; but these "prescribed regulations," as they are to be called, must be approved by the Local Government Board. On the other hand, the Act provides that any expense to which the owner is put through the operation of the Act shall be met by compensation from the district council and this constitutes the gist of the whole difficulty. It was thought that under such regulations the Jones's homes could either be closed or so completely transformed as to cease to be a constant cause of complaint, though the presence of consumptive patients in the streets, especially when they are paupers, may always constitute a source of complaint. The only other clause existing that might be invoked in regard to existing homes in the absence of regulations is Paragraph A of Section 3, Subsection 7, which says that the licence may be refused if "the person applying for such grant or renewal (of licence) is not a fit person to be licensed to keep a hospital for disease." This, however, might involve expensive litigation.

Unfortunately there is no legal definition as to who is or is not competent to manage a hospital. There is nothing to show that the Jones family possess any sort of technical qualification, but the same may be said of the lay committees of management of many hospitals of this country, and Mr. Jones is believed to be advised by a medical man. Thus the only course of action was to draw up regulations; on the other hand, what sort of regulations could be drawn up that could be effective without giving the Jones family the right to claim compensation? Then there was also the fear that what with licensing and regulating these homes would end by being established in a permanent and legal way; whereas the inhabitants are really only desirous of getting completely rid of such institutions. Therefore, instead of regulating, which might result in perpetuating, it seemed that it would be better to buy out the Jones family and to adopt regulations for new homes that would prevent the recurrence of a similar grievance. This the Act sanctions and leaves it as a matter of agreement. But the owners asked far too high a price, particularly as the premises would have to be disinfected and done up anew in every respect. On the other hand, as Section 233 of the Public Health Act of 1875 is applied to loans under this new Sandgate Act moneys could be borrowed and the repayment spread over a number of years.

In arguing in favour of purchase Mr. Brockman, in his report to the council, said:—

> When once the stigma of Sandgate as a colony for consumptive patients is removed there is no reason why the value of the properties should not increase, and it therefore seems not improbable that in the long run there will be little or no serious loss to them.

He therefore urged the council to use the Act so as to remove from the town ..

> the stigma of being little better than an aggregation of pauper consumptive hospitals, for that is the exaggerated view of the outside public. I know, and may well tell you, that until you make it impossible for any such establishments as those of the Jones family to exist in Sandgate the place will be avoided as if it were plague-stricken by the class of visitor whom you desire to attract to the town.

In such circumstances, he added, any sum in compensation would be well spent as an absolute insurance against such evils as the town had suffered from for the last ten to 15 years.

From the above it will be seen that there were two courses open to the Sandgate district council. First, to draw up regulations and to enforce them; and secondly, to buy the Jones's homes. The remarkable fact remains that the council would gladly follow either course and yet has not been able to do anything whatsoever. Before any attempt was made to secure a special Act of Parliament the Local Government Board was consulted on the subject and the Sandgate authorities imagined that their plan had been approved. But when the Local Government Board experts appeared before the House of Lords and the House of Commons committees their evidence was hostile on public grounds. It was not anticipated, however, that when once the Bill was passed and became law there would be any difficulty about the regulations. The question of compensation was the only difficulty that troubled the authorities; but the clerk argued that the regulations would not prevent the homes being used for convalescents. The compensation would depend first on evidence being forthcoming that as homes for consumptives they were paying concerns. Then it would be necessary to show what the loss might be if they were converted into homes for convalescents, though this might give rise to expensive litigation. The convalescents pay 17*s.* 6*d.* per week, and the patients suffering from tuberculosis pay 21*s.* per week, but then the latter are supposed to cost much more to keep. Therefore, if the homes were as well filled with convalescents as they are with tuberculous patients there should be hardly any loss at all, but the paupers would still figure in the streets of Sandgate.

These suggestions evoked, however, great hostility on the part of many inhabitants of Sandgate. The object of not a few property owners is to get rid of the homes altogether, and this because of their pauper inmates. The allegation that many of the paupers are dangerous neighbours, because they might spit in the streets and spread tuberculosis, was utilised as a strong argument against the homes. Nevertheless, if no more tuberculous patients were received at the homes the fact that some 200 paupers, from all parts of England, but principally from London, are crowded together in a small town of less than 2000 inhabitants is their principal grievance. How can the inhabitants of Sandgate attract visitors or the families of the officers quartered close at hand in Shorncliffe camp when out of every ten persons living in this small community one of them is a pauper, even though he be only a convalescent and not a tuberculous pauper? In spite of all these objections the council determined to apply the special Act. Under this law the Jones family sent in applications for licences to receive tuberculous patients in six of their homes. At the same time—namely in December, 1905—the Sandgate council forwarded to the Local Government Board a draft of the "prescribed regulations" which it proposed to enforce as the conditions for granting licences. This project of by-laws was returned on Dec. 13th, the Local Government Board asking that certain clauses should be struck out. This was done and the project sent back on the 20th, it being necessary not to lose time, as the licences would have to be granted or refused on the 20th of the following month.

While seeking to obtain the consent of the Local Government Board to the regulations, negotiations for purchase were opened with the Jones family and it is said that £10,000 were offered. In January, 1906, the Jones family, however, insisted that this sum would not cover the mortgage on the estate. The council added another £2000 for goodwill and compensation, though it was not satisfied that the property was worth more than £10,000. Indeed, it was thought very doubtful whether this sum would ever be recovered. In any case the council would have to hold the property for a very long time, and unless it succeeded in letting it this would entail a heavy loss. While these efforts to purchase were thus proving abortive the negotiations with the Local Government Board were not making any better progress. On Jan. 5th, 1906, the Board wrote asking for information on numerous points. It desired to have a list of the applicants for licences, then inquired if the premises could be made to comply with the proposed regulations, and, if not, wanted full particulars, the result being to show that the regulations would entail the closing of all the homes. Finally, the Local Government Board added that all these matters could not possibly be concluded before Jan. 20th when the licences must be refused or granted. Therefore the Sandgate council would have to consider the applications without reference to regulations. Thus was the council left in a hopeless difficulty. It could not purchase the homes at the price required; it could not regulate the homes in the sense suggested by the drastic draft regulations, since the Local Government Board had not sanctioned them or placed the homes on the same level as small-pox hospitals, nor could the council refuse to license the homes on the ground of their not complying with the regulations, since no regulations existed. Then had such a refusal been made the whole question of compensation would be raised and the council could not say why it refused to license. If a licence was refused, except on a ground mentioned in the Act, the applicant could get his licence by appeal, to quarter sessions. The Local Government Board expresses its willingness to sanction reasonable regulations, but any increase of cubic space would decrease the number of patients to be received in the homes and prejudice the question of compensation. However, the council did refuse to license one of the homes—namely, Ontario House. The council took this course in regard to this house because the house was not used for tuberculous patients when the matter was before the House of Lords and there could in consequence under the provisions of the Act be no claim for compensation for refusal to license. But the five other houses were already inhabited by tuberculous patients and therefore if they were not licensed a claim for compensation might be entered. Thus five of the Jones's homes were licensed and the licence ran from March 1st, 1906, to March 1st, 1907.

Having failed to obtain regulations in time the Sandgate council let the matter remain in abeyance for a little while. In March, 1906, the Local Government Board wrote saying that before sanctioning any regulations it wished to hold a general inquiry and that they should first be considered with regard to hospitals or homes destined to receive tuberculous patients in the future, leaving existing sanatoriums to be dealt with separately. Such inquiries are always held as a matter of law and of justice. The Sandgate council replied that, as the summer season was approaching, it strongly objected to a public inquiry which would not fail to frighten away the few visitors who still came to Sandgate and whose presence saved the town from total ruin. Besides, the council was not concerned in devising plans for the construction of hospitals in the future; its object was to close the homes or hospitals that had been established in the past.

While these matters were pending a very serious revelation was made through the Charity Organisation Society. The clerk of the Sandgate council communicated the facts to the Local Government Board on May 29th, 1906. It appears that no sooner were the Jones's homes licensed than letters were written to various boards of guardians inferring that these homes were now all that could possibly be desired because they were licensed and could not have been licensed unless they had conformed to the regulations drawn up by the Sandgate urban council and approved by the Local Government Board. The Board, of course, had no idea of approving or recommending the Jones's homes any more than it recommends common lodging-houses or public-houses that are also licensed. Thus I have before me the text of the letter sent to the Lambeth and the Poplar boards of guardians. At the top in red ink is the following inscription.

> NOTE.—Our Sanatoria for Consumptives are now licensed by the Local Sanitary Authority, under Act of Parliament 5, Edw. 7th, xxx., Ch. clxxxiii., and are also subject to inspection by the Medical Officer of Health for Sandgate.

It need scarcely be pointed out that this note is as correct in letter as it is incorrect in spirit, for the Act quoted has not made the slightest difference in the condition of the homes, and the medical officer of health has no right of entry at night when inspection is most needed. The letter, after mentioning the new Act, says:

> The district council have power to make resolutions subject to the approval of the Local Government Board as to the structure, drainage, and ventilation, the number of patients to be accommodated, and as to the general administration of the homes; and, further, that the medical officer of health for Sandgate has authority to inspect our institutions at any time in the future. We believe that our homes are the only establishments of the kind which have been licensed by a local authority under an Act of Parliament. We should be greatly obliged if you would kindly bring this information to the notice of your guardians.

These letters were addressed to the clerks of the guardians and are signed "The Sandgate Seaside Sanatoria, P. Elvin Rickard, secretary."

Another letter was sent in May, 1906, to the boards of guardians of Faversham, Bristol, and Dudley, and probably many other authorities containing similar assertions to those made above and also this paragraph—

> It is now acknowledged that patients, especially those in the incipient stage, derive material benefit and are sometimes cured by the fundamental remedies—viz., the employment of fresh air and sunshine, of good food, and of regulated hours of exercise and rest—and these are important features at our institutions.

At the recent hearing these assertions were scarcely confirmed by some of the witnesses who had been inmates of the homes in question. Also, it would appear that the Bristol board of guardians was not altogether satisfied, for it wrote for further information and Mr. P. Harold Jones, who signs as "Manager," answered. His letter, dated May 28th, says:—

> The writer was not aware that your board had sent two patients to Sandgate some few years ago, as the present institutions have only been under his control and management for the last two years, during which period you will observe that they have been licensed for the reception of consumptive patients under an Act of Parliament, and are subject to certain regulations of the district council here, whose power extends also to administration generally.

This letter is not so skilfully worded. Instead of saying that the council has the power to make regulations, and leaving the reader to infer that such regulations have been made and enforced, Mr. P. Harold Jones wrote that his homes "are subject to certain regulations of the district council here, whose power extends also to administration generally." This is incorrect, for there are no such regulations in existence; and, in the absence of such regulations, how can the council interfere with the management of the homes? The only change that has taken place in consequence of the new Act is that the Jones family have had, in applying for licences, to supply details as to the buildings in which they proposed to receive tuberculous patients. But in the absence of any sort of regulations or rules the council could not object to any of the homes. The council is of opinion, for instance, that there should be more space outside the homes and that inside they are overcrowded, but as there are no regulations whatsoever dealing with the question of surrounding space and overcrowding what could the council do?

Thus it will be seen that the special Act of Parliament instead of, as anticipated, reforming the Jones's homes out of existence has simply improved and strengthened their position by making it appear as if they were licensed under regulations in which all the greater reliance might be reposed since they had to be approved by the Local Government Board. In reality no such regulations exist; no improvement has been effected as a result. On Sept. 12th Mr. J. S. Atkinson, the new clerk of the Sandgate council, wrote again to the Local Government Board summarising the whole position in regard to the new Act—namely, that Sandgate was a small place ill able to afford the £3000 which the Act had cost and that the Jones's homes were absolutely unsuitable as hospitals for the treatment of tuberculosis, especially considering the poor character of the patients, the absence of any effective control, and the necessity of making a profit out of the small sum paid by the guardians for the paupers whom they sent down. Of course, the same may be said concerning private sanatoriums in different parts of the country. Then on Nov. 2nd the Sandgate council wrote again saying that the time was approaching for the renewal of the licences and that the question of the regulations to be enforced must be decided. On the ensuing 27th the Board replied that it had attended to the matter but found a difficulty in dealing with the draft regulations, so it would send one of its medical inspectors and its architect to visit the homes. In other words, it would hold an informal conference instead of a public inquiry. Accordingly, on Dec. 20th, 1906, Dr. H. T. Bulstrode of the medical department, and Mr. Kitchin, architect of the Local Government Board, arrived at Sandgate. Mr. Jones was informed of the visit and the text of the regulations which the Sandgate council had proposed was shown to him as a matter of fairness.

The Sandgate council, according to the opinions expressed to me by officials in authority, was deeply disappointed with the attitude and views of the representatives of the Local Government Board. The Local Government Board, it was gathered, would not sanction any regulations that in application would probably result in closing one or more of the existing homes. The reason for this is perfectly clear. The Local Government Board, having the public health administration of the whole country in its hands, must look at the general effect of any special action taken. Regulations which would have led to the closing of all the homes at Sandgate, if applied generally, would cause the abolition of half the hospitals for tuberculosis in this country, and many of these institutions are rendering invaluable service though not perfect in structure.

SOME TURKISH LAZARETS

AND OTHER SANITARY INSTITUTIONS IN THE NEAR EAST.

VIII.[1]

THE SANITATION AND WATER-SUPPLY OF JEDDAH.

The Importance of Jeddah as a Port of Pilgrimage; its Population.—Lodgings for Pilgrims.—Difficulties in Conservancy.—State of the Town at the Height of the Pilgrim Season.—Type of House in Jeddah.—Municipal Hospital for Ordinary Diseases.—Shed for Cholera or Plague Patients.—Need of Two New Hospitals.—Spring Waters; the Three Principal Sources; Conduits Damaged by Bedouins.—Tank Waters.

IN the preceding articles I have dealt at length, but not, I trust, at so great a length as to be wearisome to the readers of THE LANCET, with the great lazaret of Camaran. In the succeeding articles I shall describe more briefly the sanitation and water-supply of Jeddah and its lazaret, Abu-Saad, and the ports of Yanbo and El Wej.

The port of Jeddah lies about half-way down the Arabian coast of the Red Sea. It is by far the largest and most important town along the whole of that coast. Commercially, it is the principal port of import and export for the whole of the Hedjaz province, but it derives its main importance from the fact that it is only 45 miles from Mecca, and is consequently the gate by which the overwhelming majority of Moslem pilgrims enter and leave that province. A certain number of pilgrims, it is true (mostly coming from the north), land at Yanbo, the port for Medina, which they visit first and thence proceed overland to Mecca. But many never go to Medina at all, and of those who do a large proportion visit Mecca first, and after the fêtes of Kurban Bairam are completed make their way to Medina, either overland from Mecca or by sea from Jeddah.

Jeddah has a permanent population estimated at about 20,000. But for quite two-thirds of the year this number is greatly increased by a floating population consisting of pilgrims going to or returning from the holy places of Islam. At the height of the pilgrim season the figure mentioned is perhaps doubled or more than doubled for several days at a time. If it be asked where this vast mass of pilgrims is lodged the reply must be that the large majority are lodged nowhere; they sleep in the streets, in the open spaces, in any nook or corner or passage where they can lay their heads. A considerable number of houses are set apart as pilgrims' lodgings, but they suffice to shelter only a small proportion of the whole. Some of these houses, known as "Rubats," are charitable institutions founded by rich and pious Moslems for the free use of their countrymen. There are several for Indian pilgrims; one of the largest was founded five years ago by the Begum of Rampur and consists of three adjoining houses made into one. Others are assigned to the use of Javanese, Malayans, and pilgrims of various nationalities. These houses are of the type of the other Jeddah houses referred to below. They are registered as lodgings for pilgrims by the local authorities and are each year cleaned and whitewashed inside before the arrival of the pilgrims. But, as just stated, they can only accommodate a small fraction of the whole number, and the rest live, cook, eat, sleep, and perform all the other ordinary functions of life in the open air. It is obvious that a town under such conditions presents many serious problems in sanitation, and I propose in this chapter to consider briefly how these problems are, or are not, solved before passing to a description of the Jeddah lazaret (better known as the lazaret of Abu-Saad-Wasta).

The sanitation of Jeddah is in the hands of a municipality. Conservancy is, perhaps, one of the most formidable difficulties with which this authority is faced, when the town is swarming with pilgrims in the manner just described. The municipality possesses only 12 conservancy carts. For the short period that elapses between successive pilgrimage seasons these may perhaps suffice. At the moment, indeed, of my arriving in Jeddah—on the actual eve of Bairam—the streets were remarkably clean. Half of the population or more had gone to Mecca for the fêtes and the town had a markedly deserted appearance. The bazâr was silent and almost empty; the few inhabitants remaining put on their best clothes (and an Arab's best clothes are very beautiful garments indeed, of soft-hued silks and cloths) and amused themselves decorously by going off to the many pilgrim ships lying idle in the roads, by visits to the mosques, or by playing games of ball in the streets and open places. Conservancy offered no great difficulty in such circumstances. A week or ten days later, when the caravans began to flow back from Mecca, the conditions were, however, very different. The bazâr, through which the main street of the town runs, became a solid mass of Oriental humanity, through which the caravans—endless streams of camels, tied head to tail, and each carrying two or more pilgrims in gigantic litters or "shugdufs"—slowly forced their way. The open squares and spaces were soon covered with pilgrims camping out, with or (mostly) without tents or other cover, pilgrims of many nationalities—Arabs, Indians, Afghans, Central Asiatics, Javanese, Malayans, Chinese, Tartars, Moors, Egyptians, and many another race. A more interesting or more picturesque sight it would not be easy to find elsewhere. The streets of Jeddah themselves are as picturesque as those of any Indian city, which is saying much, and peopled with this many-hued and diverse-featured crowd of Hajjis fresh from Mecca they form a spectacle that is perhaps unique in the world.

But, to return to the sanitary aspect of the matter—the only aspect that can be considered here—it soon became evident that the provision made for the sanitary wants of this vast crowd was sadly inadequate. Public latrines and urinals are almost wholly wanting; the pilgrims attended to the calls of nature anywhere and everywhere. The 12 conservancy carts, though working night and day, seemed to make no impression on the truly lamentable condition of the streets and open spaces. Human excreta lay about on every side, and as thousands of fresh pilgrims kept pouring into the town more quickly than the daily departing pilgrim steamers could remove them the conditions became more and more offensive.

The provision of water to this fluctuating population is another problem presenting peculiar difficulties in this comparatively rainless region; but as the water-supply of Jeddah is a somewhat complex question and one of which I endeavoured to make rather a special study it will be dealt with in some detail.

---

[1] Nos. I., II., III., IV., V., VI., and VII. were published in THE LANCET of April 27th (p. 1188), May 4th (p. 1251), 11th (p. 1317), and 18th (p. 1389), and June 1st (p. 1516), 8th (p. 1607), and 22nd (p. 1741), 1907, respectively.

The houses of Jeddah are usually large and several storeys in height. They are mostly built of the madreporic stone found in the neighbourhood, covered outside with a lime-plaster. The projecting windows and balconies are of wood, elaborately carved in fantastic and often beautiful designs, giving to the narrow streets that strikingly picturesque appearance to which I referred above. Many of the larger houses, known as "hoches," have one or more courtyards and consist of vast warehouses (for grain, carpets, dates, and all other kinds of merchandise), shops, and dwelling-rooms, all more or less under the same roof. The dwelling-rooms in many instances (but by no means in all) are rather small and dark. The closet is usually in a dark and badly ventilated corner; the excreta pass thence to a cesspool in the courtyard. In many of the courtyards there is a shallow well, and in some a rain-water cistern, of which mention will be made later.

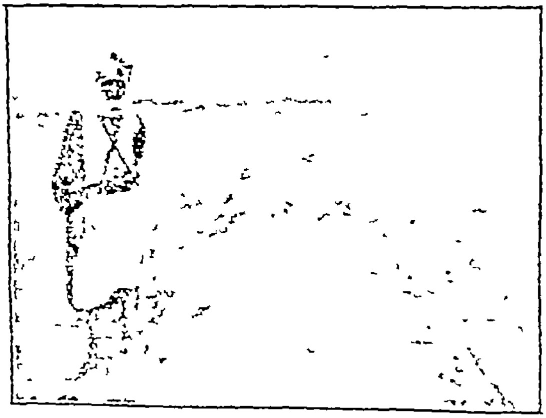
The hospital accommodation provided in Jeddah is quite inadequate to the needs of the place. There is a small municipal hospital situated just inside the wall that completely surrounds the town on its eastern side and not far from the Mecca Gate. It is a one-storey structure built against the town wall. It contains two small wards for 12 and eight patients respectively; the wards have no flooring, their floors being of beaten earth. Close by is a wooden shed in bad condition used for dysenteric patients; it is almost entirely without furniture. In brief, this hospital—though those in immediate charge of it have apparently done their best with the limited means placed at their disposal—is altogether too small and too primitive for a town like Jeddah, with its vast floating population. The Inspection Commission in its report consequently urges the Turkish Government to build a large general hospital capable of holding 150 or 200 sick and suggests a suitable site where it might be built. It further points out that the occasion would lend itself admirably to the generosity of some rich and pious Moslem (and there are many such in eastern countries) who could do no more useful act to his fellow believers than to found and to endow a good hospital in Jeddah. Whether this suggestion will ever bear fruit time alone can show.

The hospital accommodation for cases of cholera, plague, or other infectious diseases is even more inadequate than for those of ordinary diseases. When plague broke out in Jeddah in 1897 a large wooden shed was put up as a plague hospital on an open space in the south-west corner of the town. The skeleton of this shed still remains. Since outbreaks of plague and cholera are by no means rare in Jeddah the Commission strongly urges the Turkish Government to put up an isolation hospital capable of holding from 30 to 40 patients. During the past summer a rather persistent epidemic of plague occurred in the town but up to the present no steps have been taken to carry out the recommendation of the Commission on this point.

The question of the water-supply of Jeddah has for years past presented difficulties and its inadequacy has been the subject of frequently repeated complaint. The town has been constantly threatened with a water famine, and what that means in a tropical climate and an insanitary town may be readily conceived. During a stay of 19 days there (the main object of which was the inspection of the Abu-Saad lazaret, to be described subsequently) it became possible to collect much interesting information on this question—information which has been embodied since my return in a printed report which has been presented to the Board of Health and which may be summarised here as follows. The water-supply of Jeddah is of three different kinds—so-called spring water, rain water collected in large tanks, and well water.

Spring water.—The sources of this water are, it would seem, rather underground collections of rain water than true springs. They are mostly situated at a considerable distance from the town. There are only three that need be mentioned here. They are the following. 1. The Aïn Hamidieh or Bir Viziєh is situated some 11 or 12 kilometres to the south-west of Jeddah. The water is, or was, brought to the town by a masonry conduit which has, however, been constantly cut and damaged by the Bedouins. It was last repaired in 1902 but was soon damaged again, and at the present time not a drop of this water reaches the town unless it be on camel back or donkey-back. It is said that the water at the source itself has sunk considerably (one of my informants said as much as two metres) below the level of the conduit. In any case the reservoirs in the town to which this water should be supplied were quite dry in February last. There are five of these reservoirs. One of them is about four and a half metres long, three and a half metres wide, and three metres deep, built in masonry, covered with plaster. This water is (or, rather, should be) conducted first to a small open reservoir by the side, where it should deposit some of its grosser solids before entering the larger cisterns. At one side there was at one time a row of taps; they no longer exist. This cistern is covered over with a roof of armoured cement in which is a man-hole; the interior was absolutely dry and the bottom littered with rubbish. The state of the other cisterns in the town was said to be much the same. A small quantity of this Hamidieh water was, as stated above, brought to the town in skins mostly carried by camels. A camel-load is reckoned at 16 small skins or four large ones. A small skin is supposed to hold about ten litres (rather over two gallons) of water. A load is therefore about 160 litres. The load of Hamidieh water was sold at 15 piastres (about half-a-crown). The quality of the water is said to be fairly good and it never becomes brackish, as do some other waters in these regions. 2. The source known as the Aïn Bariman is situated to the north of the town some five hours (others said eight hours) away. In passing it may be stated that the wish to visit any of these sources was impossible of fulfilment. Since the attack by Arabs on the foreign Consuls in 1895, when the British Vice-Consul was killed and several of the Consuls were wounded, the Turkish authorities permit no Europeans to go any distance outside the town, and even when permitted to go a short way into the desert they must be accompanied by an armed escort. This source is said to be in the form of a large, deep well; there is no conduit and the water is brought to the town in old petroleum tins (which are considered preferable to skins) by camels or donkeys. It is said to be the best of the waters supplied to Jeddah, but the yield is small—not more than five or six tons a day—and the price is relatively high. A petroleum tin (it may be added, in passing, that in the Near East there is almost no use to which an empty petroleum tin may not be put) is reckoned to hold about 17 or 18 litres; a tin of Bariman water sells for two and a half piastres; a load of 160 litres would therefore cost 22 or 23 piastres (say 3*s*. 10*d*.). 3 The Aïn-Faradj-Yassur is situated six or seven hours to the east of Jeddah. It has a large conduit, which is seen in Fig. 28; it is of masonry and its inner dimensions are about 32 inches by 20 inches. It is constantly being damaged by the Bedouins or others; the photograph was taken purposely at a spot where such damage can be seen; the last time it was repaired was in 1899. The conduit enters the town close to the Mecca Gate, where it passes through the bottom of a deep wall and is thence continued to a central depôt situated in what is known as the Yemen quarter of the town. A portion of this depôt is seen in Fig. 29. It has the form of a deep square depression or pit, about 20 feet square and some 25 feet deep, with masonry walls, covered with plaster. At the bottom, all round the walls, is a series of small reservoirs in cement. A wide stone

FIG. 28.



Conduit outside Jeddah damaged by Bedouins.

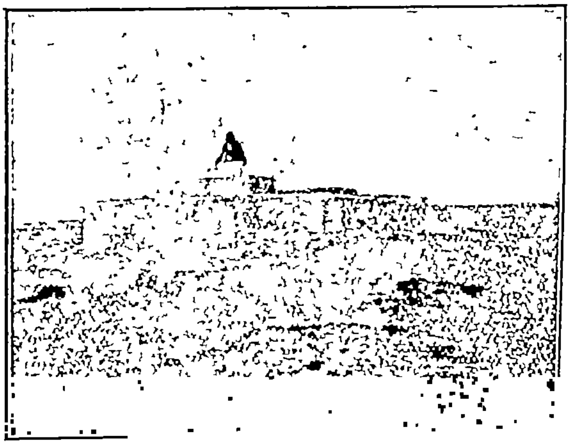
staircase leads down to them. When I visited the depôt the reservoirs were completely empty; the door leading to the stair was locked, and the bottom of the depôt, as also the reservoirs, was littered with débris and rubbish. The quality of this water is said to have been good; it was sold at one and a half piastres the small skin.

FIG. 29.

Reservoirs for Ain-Faradj-Yassur water, Jeddah.

Tank water.—One of the most striking features in the desert outside Arab towns, such as Jeddah, Yanbo, or El Wej, is the presence of vast masonry tanks or cisterns, more than half underground, and intended to hold and to store rain-water. Rain is comparatively rare in these regions, but when it does fall it usually falls in large quantities, and these tanks are constructed of a size and in number sufficient to hold two, or even three, years' supply. The external appearance of one of these cisterns is seen in Fig. 30.

FIG. 30.



Rain-water tank ("Sahrij") outside Jeddah.

They are large, often immense, structures in masonry, coated with plaster outside and with cement or "tap-tap"[2] inside, and roofed over with a masonry arch, in which there are usually several manholes. The largest tank that I saw was about 40 metres (130 feet) long and 12 metres (40 feet) wide; others are said to be still larger. These tanks are intended to collect the rain water from the surface of the desert around them; there are no actual conduits to collect the water but it can generally be seen that the sandy surface has been worked more or less all round, forming channels and low embankments, and here and there are rudimentary works in masonry, all intended to direct the flow of the surface water towards the cisterns. At one end or one side of the cistern is a small open reservoir (sometimes there are several) where the waters first collect and deposit their grosser solids. I visited the interior of one of these tanks (in the desert near Yanbo). The entrance was by a door leading to a stone staircase, which descended to the bottom of the cistern; the total depth was about seven metres (22 feet). At that time there was only about a foot of water, but, the cistern being a very large one, that was equivalent to about 120 tons. The water appeared fairly clean; it was mainly drunk by the troops garrisoned close to the Medina Gate of Yanbo. Officers and men assured me that the water was then quite good but that it would steadily deteriorate during the summer and that if no rains fell in the winter there would be danger of a water famine. Fortunately, heavy rains fell in November all along the Arabian coasts of the Red Sea and both at Yanbo and at Jeddah the tanks must be now well filled again. At Jeddah, at the time of my visit, the tank water was nearly exhausted; it had frequently a bad smell; and during the past summer I learned from letters that it had become absolutely intolerable. Most of these tanks belong to private individuals who make a good income from the sale of the water. These persons are said hitherto to have opposed every effort to supply Jeddah with a purer water and it is more than probable that the damage to the conduits of the spring waters (referred to above) is by no means always done by Bedouins, but may sometimes be ascribed to tank owners jealous of competition. There are a few small tanks in the town itself situated in the courtyards of the houses. They usually collect the rain-water from the roofs, but some houses have large cisterns which are filled by water brought into the town from the sources or springs outside.

(To be continued.)

BIRMINGHAM.

(FROM OUR OWN CORRESPONDENT.)

The University.

THE medical examinations are now over and the greater part of the ordinary work of the summer session is finished. One candidate, L. G. J. Mackey, secured the M.D. degree. At the final examination for M.B., Ch.B. eight candidates succeeding in passing the examiners, and James Fenton was awarded both the Ingleby scholarship, for highest marks in gynæcology and midwifery, and the Queen's scholarship, for the highest place in the examination. Seven candidates passed the fourth examination and John Dale, who was placed in the first class, gained the Queen's scholarship. In the third examination, which includes pathology and materia medica and pharmacy, nine candidates passed, and the Queen's scholarship for highest place was awarded to Herbert Henry Sampson. In the second examination six candidates passed and O. M. Holden secured the Queen's scholarship. The Board of Education has approved the proposal of the University to take over the residential part of Queen's College for the purposes of a residential hall for students of the University. The experiment will therefore proceed and if it is successful it will have far-reaching and very beneficial effects on the University life of future students. Professor Kirkaldy, who has already shown so much interest in the social welfare of the students, will be warden, and this is a sufficient guarantee that everything will be done on the highest possible lines. There will be accommodation for about 40 students and the fee will be 20 guineas a term. Students who are wise and who wish to obtain all the benefits of university life should secure rooms as soon as possible, and parents who wish their sons to live in the city during the terms should not miss the opportunity of securing places for them in the hostel.—The golf match between the University and the city has resulted this year in a victory for the University.

The Hospital Saturday Fund.

Nominally June 15th was Hospital Saturday but actually the collection of the money extends over several weeks and it is not yet certain what the total amount will be. For several years the committee has endeavoured to raise the collection to £20,000, and year by year it has gradually risen until last year it was only £700 short of the desired sum. This year the hopes of the committee are high, for the early returns have been very favourable and some of the subscriptions have been greatly increased; on the other hand, however, there are some notable diminutions which have necessarily followed from alterations in trade, circumstances which must always occur in a busy manufacturing centre, but on Saturday last the total amount had already reached the sum of £18,329 1s. 9d. The committee gives £10,000 each year to the local hospitals, sends consumptive patients to St. Leonards, and maintains convalescent homes in which 3035 patients were received last year. It is obvious that the collection of so large a total, which is made up of multitudinous small sums, is only secured by a large amount of work and excellent organisation, for which Sir William Cook and his committee deserve the sincere thanks of the city.

---

[2] The nature of "tap-tap," as employed for roofings, was described in an earlier article (May 11th, p. 1320); its composition when used for lining tanks is slightly different.

The Royal Institution for Deaf and Dumb Children.

The annual report of the above institution is a record of successful work upon which the committee can be congratulated and for which it deserves better support than is indicated by an excess of expenditure over ordinary income to the extent of £118, and that after £250 had been transferred from legacies and special donations to income account to meet the requirements of the Board of Education that one-third of the annual expenditure shall be derived from voluntary subscriptions if the certificate of the society is to be continued. The institution deserves better support, for it prepares children to make their own livings when they leave at 16 years of age and very few of those who have passed through it have failed in after life.

The Wolverhampton Nursing Institution.

This institution has had another successful year which left it with a balance of £42 at the end of April last. It maintains a staff of 33 trained nurses and during the year it treated 302 cases which were under the care of 85 medical men. The committee of its district nursing branch has decided to establish a centre for the training of pupils for the examinations of the Central Midwives Board and at a recent meeting it was stated that the legacy left by the late Miss Perry would enable the institution to purchase more land close to the institution and to erect additional buildings; it may be presumed, therefore, that the scope of the institution's work will be increased.

The Necessity for Better Mortuary Accommodation at Rugby.

If the account published in one of the daily papers is correct in all details the authorities at Rugby have failed to appreciate their duties and should take the matter of proper mortuary accommodation in hand at once, for it is stated that the room at the cemetery, in which a post-mortem examination had to be made, was so badly lighted that the door had to be left open, exposing the operating table to the public gaze. This is certainly a condition of things which ought not to be tolerated at the present day.

June 25th.

LIVERPOOL.

(FROM OUR OWN CORRESPONDENT.)

Reception at the University of Liverpool.

AN exceedingly interesting social gathering, in the form of a reception, took place at the university on June 14th. Invitations to inspect the admirably arranged group of buildings had been sent to the Lord Mayor and Lady Mayoress, the members of the city council, members of the education committee, the head-masters and head-mistresses of secondary schools, and to others interested in higher education. The guests were received by the Pro-Chancellor and the Vice-Chancellor. All the buildings were thrown open for inspection and members of the University staff were present in each department to explain everything on exhibition. The various laboratories attracted keen attention, the Thompson-Yates and Johnston laboratories (pathology and physiology) proving especially engrossing, while the zoological section controlled by Professor Herdman claimed general notice. An exceptionally interesting feature of the proceedings was the exhibition of a series of experiments with liquid air given by Professor Wilberforce in the physics theatre. This department was controlled for upwards of 20 years by Sir Oliver Lodge.

The Prevention of Hospital Abuse.

The principal Liverpool hospitals, with one exception, have agreed to hold a conference with the view to prevent the abuse of charity by persons able to pay for medical treatment. The question is one of interest not only to managers of hospitals but also to members of the medical profession. The object of the conference is to discover whether there is an abuse of charity and, if so, to what extent. Unless all the hospitals fall into line as to a united course of action a satisfactory solution of the difficulty cannot be clearly obtained. The fact of one hospital not making inquiry as to the means of applicants will swell the statistics of attendances at that particular charity, whilst probably reducing those at other hospitals. A wrong impression may thereby be given to the philanthropic of the respective usefulness of the different charities. It is to be hoped that the committee of the unwilling hospital will reconsider its position in the matter, especially as the other hospitals are acting purely for the public weal.

The Health Committee: Notification of Anthrax; Health Statistics.

The following resolution of the city council was approved by the Local Government Board on June 11th:—

> That the council as the urban sanitary authority of the city of Liverpool do order that the provisions of the Infectious Disease (Notification) Act, 1889, shall apply in their district for three years to anthrax and that such order shall come into operation immediately after the expiration of one week after the publication of the first advertisement of the order as approved by the Local Government Board.

At the last meeting of the health committee the medical officer of health reported that the death-rate of the city was only 16·2 per 1000, as against 16·4 per 1000 at the same period of last year.

Providence Hospital, St. Helens.

The annual report of the *Providence Hospital*, St. Helens, has been issued, in which the treasurer records the fact that systematic voluntary weekly collections have now been organised at several of the workshops and manufactories in the town and also at one of the large collieries in the neighbourhood. Already considerable assistance has been obtained by this means and it is hoped that arrangements may shortly be completed for bringing the whole of the works into the scheme. Included in the hospital receipts is a sum of £366 1s. 6d., representing the penny a week subscriptions which are collected by a band of ladies, the amount representing 87,858 pennies.

June 25th.

SCOTLAND.

(FROM OUR OWN CORRESPONDENTS.)

Appointments to the Staff of the Edinburgh Royal Infirmary.

AT the meeting of the board of managers of the Edinburgh Royal Infirmary held on June 24th, Dr. D. O. Watson was elected junior assistant physician, and Mr. W. J. Stuart, F.R.C.S. Edin., junior assistant surgeon to the institution. Much interest was taken in the somewhat keen contest for these posts.

Memorial to Dr. James Finlayson.

The anniversary of the opening of Trinity Church Children's Convalescent Home was held at Ravenscraig last Saturday afternoon, when a ward was inaugurated in memory of the late Dr. James Finlayson. The home, which has now been open for 17 years, was established for the benefit of the sick children of the city of Glasgow, and during that time over 2200 children have passed through it. The home has from its inception been associated with the Sick Children's Hospital and under its direct medical control. The annual expense of maintaining the home amounts to £300, which is met by the members of Trinity Church. Sir Hector Cameron in naming the new ward after Dr. Finlayson referred to his valuable services to the home during the last 17 years. He thought it was peculiarly appropriate that a ward in a children's convalescent home should be permanently associated with the name of Dr. Finlayson. By his work and contributions to the literature of the subject he was recognised as one of the leading authorities on children's diseases and he had been one of the first to support the establishment and equipment of children's hospitals. At a later part of the proceedings a portrait of Dr. Finlayson was unveiled.

The Sanitary Association of Scotland.

The annual congress of the Sanitary Inspectors' Association of Scotland was held last week at Dunoon, when the President, Mr. George Dunne, delivered an address on Sanitary Progress and Holiday Resorts. Papers were also read on Some Aspects of the Food and Drugs Act and the Ventilation of Sewers and Drains. Visits were paid to the hospitals, waterworks, and refuse destructor of the district.

National Conference on Sweated Industries.

A good deal of interest is being taken in the arrangements which are being made for the National Conference on Sweated Industries to be held in Glasgow on Oct. 11th and 12th. Seeing that the subject bears so directly on public health, housing, and general sanitation, it is to be hoped that as the result of the conference some legislative remedies may be suggested to deal with the evil.

Suggested Case of Ptomaine Poisoning.

In the Court of Session a rather curious case has arisen where interdict is sought by the proprietors of a Glasgow restaurant to prevent the widow of a man recently dead from circulating a statement that her husband's death was attributable to ptomaine poisoning consequent upon his having partaken of food supplied in the restaurant. The first intimation received by the complainers was a claim for £10,000 by the respondent in respect of the death of her husband, which took place on May 27th as the alleged result of a lunch partaken of on May 17th. The claim was made and the story circulated without any inquiry being made of the proprietors of the restaurant, who state that the soup was made fresh on that day, of the best material, and supplied to over 100 customers without a word of complaint. Further, on examining the body of the deceased after exhumation, death was found to be due to cerebral hæmorrhage.

Competency of a Ship's Surgeon.

A case has been decided in Glasgow Sheriff Court in which a seaman sued a firm of ship-owners for £400 as reparation in respect of loss, injury, and damage sustained on board one of their steamers. The case for the pursuer is that he was dashed by a wave against an iron ladder and injured. The ship's surgeon who saw him on several occasions said that he was suffering from bruises, but after his return he was treated in an infirmary for compound fracture and dislocation of the shoulder. The pursuer held that the defenders were liable in reparation on the ground that the surgeon was incompetent and that with ordinary care he could have properly diagnosed the injury; also that it was the duty of the defenders to appoint a surgeon of skill. In dismissing the case as irrelevant the sheriff said that the Merchant Shipping Act, 1904, Section 209, directed defenders to carry a duly qualified medical man, and it was admitted that the ship's surgeon was a qualified practitioner. That being so, the sheriff thought the statement of the pursuer would need to go a great deal further before he disclosed a case for inquiry.

Death of Mr. George P. Alexander, Forfar.

Mr. George P. Alexander, Forfar's oldest medical practitioner, recently died with startling suddenness at his residence. He had been out visiting a patient and while returning home he became suddenly ill, and was carried to his house where he expired almost immediately. Death was due to heart failure. The deceased was a native of Dundee and attended the University of Glasgow. Early in his career he settled in Forfar and acquired an extensive practice in the burgh. In the volunteer movement he evinced a deep interest and retired last year with the rank of surgeon-lieutenant-colonel of the 2nd V.B R.H. (Black Watch). Mr. Alexander was also a life director and a visiting surgeon of the Forfar Infirmary. He was 72 years of age and is survived by a widow, three sons, and a daughter.

Handsome Gift to Paisley Infirmary.

The honorary secretary of Paisley Royal Alexandra Infirmary has received a cheque for £3750 from the agents of Mrs. Borra Paterson, Buenos Ayres, for the endowment of three beds in the hospital. One of the beds is to be dedicated to the memory of Robert Coats Paterson (a native of Paisley) who died at Buenos Ayres in February, 1906, and the others are to be in memory of his father and mother.

Appointment of Medical Officers for Stornoway.

Dr. D. Murray (Stornoway) and Dr. Mackinnon (Stornoway) have been appointed by the Stornoway parish council to fill the vacancy caused by the death of Dr. Macdonald, medical officer of the Landward division. The Local Government Board had approved of the council's proposal to appoint separate officers for the two wards of the Landward division, apportioning the present salary equally between them. Dr. Murray was appointed for the Point and Dr. Mackinnon for the Back district.

Aberdeen: Low Death-rate among Infants.

The death-rate per 1000 in May last among children under one year of age was 70·73, as compared with the average for May in the previous five years of 142·72. Dr. Matthew Hay, medical officer of health of Aberdeen, in his monthly report states that the deaths from tuberculous meningitis reached a higher level last month than in any preceding recent month and is a little significant in view of the occurrence of cerebro-spinal fever in Scotland. Every suspicious case of cerebral illness was examined by lumbar puncture when permitted, but in no case was the germ characteristic of cerebro-spinal fever found. No connexion was known to exist between the children who died from tuberculous meningitis during the month. None of the cases died with much suddenness, the shortest duration or obvious illness in any case being seven days. In the others it varied from 14 days to three months.

June 24th.

IRELAND.

(From our own Correspondents.)

Death of Dr. E. H. Bennett.

In Dr. Edward Hallaran Bennett, one of the few Honorary Fellows of the Royal College of Surgeons of England, the medical profession has lost a very distinguished exponent of our art and science. The funeral took place on Monday last, June 24th, at Mount Jerome Cemetery, the funeral service being performed by the Rev. Charles Dowse, rector of Christ Church, Leeson Park. A number of students of the Medical School of Trinity College, Dublin, in which the deceased was professor of surgery, walked in procession behind the hearse, while the Royal College of Surgeons in Ireland, of which Dr. Bennett was formerly President, was represented by the present president, Mr. H. R. Swanzy, and many members of the council of the College as well as Mr. J. Barton, the secretary, and Mr. G. F. Blake, the registrar.

Health of Belfast.

It is to be regretted that both in number and in severity the cases of cerebro-spinal fever in Belfast show no improvement. At a meeting of the public health committee held on June 20th it was reported that there had been 17 cases of the disease during the week ending June 15th, as compared with 13 for the previous week, while since June 13th 17 cases have been reported. During the week ended June 15th 15 deaths occurred from the disease. Of 81 patients in Purdysburn infectious hospital during the week, 36 were suffering from cerebro-spinal fever and four deaths took place. Cases of measles are also at present on the increase in Belfast. The medical officer of health has reported difficulty in obtaining a suitable house for the purpose of establishing a dispensary for dealing with consumption, as owing to objections having been raised the authorities were prevented from occupying the premises selected by the committee in Great Victoria-street. "It appeared [as it is reported in the public press] that a great deal of the opposition to the proposed dispensary arose from medical gentlemen." A subcommittee was therefore appointed to look out for another house. The facts are as follows. The public health authorities entered into negotiation with an agent for a house in a terrace in Great Victoria-street, a residential district, where a good many members of the medical profession live, and the matter was almost settled, when it came to the ears of the owners that the people in the neighbourhood—not medical men alone, but a large number of the inhabitants—objected very strongly, and as a consequence the negotiations were broken off. What really prevented the house being let for the purpose was the risk of a consumptive dispensary injuring the letting value of the houses. Now that the corporation has entered into an arrangement with the Forster Green Hospital to admit consumptive patients the wise thing would be to utilise the existing dispensary in connexion with that institution and not to spend money in establishing another one.—Owing to the evidence brought before the Health Commission in regard to the state of the Belfast ashpits the health committee wisely threw out the suggestion of replacing them by ashbins and it summoned a number of rent agents to discuss the matter. On June 20th the chief clerk read a letter from a firm of rent agents. to the effect that they considered that ashpits, if properly covered and fitted with cleaning doors in the yards, would be much safer than portable bins, particularly in small property. They had introduced the bin already into some better-class property and it had not given satisfaction. Therefore they were not prepared to fall in with the proposal to adopt the dustbin in place of the ashpit. If something could be done to compel some tenants to keep themselves and their houses cleaner it would, in their opinion, have the effect of considerably improving the health of the city.

The Weather.

Not for many years—some say since 1879—has there been such a wet cold summer in the North of Ireland, and, unfortunately, there is up to the present no prospect of any change. The farmers are complaining very much of the injury being done to their crops, especially to potatoes.

Death of Mr. James May Elliott, L.R.C.P. & S. Edin.

It is with sincere regret that I record the death at his residence, Rathfriland, county Down, of Mr. James May Elliott after a long and painful illness, during which he showed the most Spartan qualities in attending to his work up to a few weeks before his decease. Mr. Elliott, who was a nephew of the late Dr. Joseph May of Rathfriland, studied in Dublin and at Anderson's College, Glasgow. After obtaining the qualifications of the Edinburgh Colleges of Surgeons and Physicians Mr. Elliott settled down in practice in Rathfriland, where for the past 26 years he has been dispensary medical officer, having succeeded in that post his uncle. A kindly, genial gentleman with a great fund of native humour, he was greatly beloved by his patients, and especially by the poor, for the extremely conscientious discharge of his varied duties. He leaves a widow and four sons; all the sons are qualifying for the learned professions.

June 25th.

PARIS.

(FROM OUR OWN CORRESPONDENT.)

Artificial Radio active Baths.

AT the Therapeutical Society M. Dupont has recently described the advantages of treatment by artificial radio-active baths. These are employed at various hot-water spas where by means of submerging the light the thermal and chemical action of the water can be combined with the therapeutic activity of the rays of the spectrum. The necessary apparatus is very simple; the wall of the bath is fitted with port-holes behind which are placed electric arc lights; coloured glass screens can be used to tint the luminous rays which can be focussed on the patient by means of lenses. This procedure permits of the employment of the ultra-violet rays of the spectrum. The same sources of light can be used for douche and luminous vapour baths.

An Auxiliary Treatment in Intestinal Perforation.

At the Academy of Medicine on June 11th M. Chantemesse described a new means in the treatment of intestinal perforations. Up to now early operation has been the only thing to be done for these conditions. The great difficulty has been to decide whether a perforation exists; the signs of perforation are those of peritonitis and often that condition is alone present. This may be guarded against by the administration of hypodermic injections of nucleinate of soda which produces a marked leucocytosis and is a good means of meeting peritonitis when that condition is declared; the pain disappears, the abdominal rigidity is diminished, and the temperature falls. The dose used is 40 cubic centimetres of a 1 per cent. solution in physiological saline. At the end of 24 hours there are sometimes slight swelling and temporary redness at the seat of injection; two or three days later a second injection is made, and still later a third in diminishing doses.

The Proposed Tour of French Watering-places and Spas for the Purpose of Medical Study.

The ninth tour for medical study will take place from August 31st to Sept. 12th of this year. It will include the eastern resorts and those of the Jura—viz., Sermaize, Vittel, Contrexéville, Martigny, Bourbonne-les-Bains, Luxeuil, Plombières, Géradmer, La Schlucht, Bussang, the Ballon d'Alsace, Besancon-Mouillère Salins, Laons-le-Saulnière, La Faucille, and Divonne. As in previous years the tour will be under the direction of Dr. Landouzy who will organise conferences at the various places on the subject of treatment by hydrotherapy. The railways will allow a reduction of half cost on all fares between the homes of those who attend and the meeting place which is to be Reims. Medical men from other countries will be allowed this reduction from the time of leaving the station where they first touch French territory, and a like reduction will be made at the end of the tour at the place of disbandment, which will be Divonne, in returning to the station from which the start was made. The whole expense from Reims to Divonne will be 300 francs, which will include railway fares, carriages, hotel accommodation, food, carriage of luggage, and gratuities. The journeys will be made by first-class special train. Eleven "travelling scholarships" (*bourses de voyages*) are to be given this year, of which one was specified by its founder to be given to an English medical man. For full information application should be made to M. Carron de la Carrière, 2, rue Lincoln, Paris. The latest day for receiving applications will be August 17th.

The Influence on the General Nutrition of the Rapid Displacement of the Air in Motoring.

At the Academy of Science on June 3rd M. Haller read a note by M. Mouneyrat in which the author studied the influence exercised by the use of the motor-car on the general nutrition of healthy people and of those suffering from anæmia and neurasthenia. His researches dealt with the number of red corpuscles and the amount of hæmoglobin and of the principal urinary constituents. Under the influence of the current of air produced by the motor the proportion of red corpuscles and of hæmoglobin increases considerably in both healthy and anæmic people, and at a moderate pace the motor affords an excellent treatment for the latter; chlorotic cases do equally well. Motor exercise has a remarkable effect on sleep, and in neurasthenics this function quickly becomes normal again. People with chronic constipation become much more regular in their habits under this influence. Gouty and arthritic cases derive marked benefit from the use of the motor-car. Patients with tuberculous lesions that are undergoing sclerosis as a rule derive considerable benefit from moderate motor-car exercise if they are careful to take it in fine weather and are protected by a glass screen. With regard to heart disease only those patients whose lesions are compensated ought to be allowed to use the motor-car and these ought never to be unaccompanied; the presence of an aneurysm, especially of the aorta, forms an absolute contra-indication to the use of the motor-car. Patients with varicose veins and hæmorrhoids do not stand it well.

Severe Gunshot Wounds of the Lung; Operation.

M. Ombredanne has had under treatment a patient suffering from a gunshot wound in the region of the heart. A little blood was escaping from the wound of entry which was situated two centimetres to the left of the left nipple. There was obviously a wound of the lung with hæmothorax, and a spinning-wheel sound (*bruit de rouet*) suggested the presence of a hæmo-pericardium. M. Ombredanne cut a flap of skin and muscle with the wound orifice in its centre, and resected the fourth, fifth, and sixth cartilages; the lung presented in the wound with a gush of black blood, and on its anterior surface was seen a hole of the size of a franc piece from which blood was spurting freely. M. Ombredanne ligatured this and a second wound that he discovered; when the pleural cavity was dried out the pericardium was found to be uninjured. The thoracic flap was replaced and sutured and a drain was placed in the pleural cavity. The patient did not make an uninterrupted recovery, but at the end of three months he had quite recovered. M. Duval has reported a very similar case with a like successful result. Both were recorded by M. Delorme at the Chirurgical Society on June 5th.

Council Meeting of the Faculty of Medicine.

The last council meeting of the Faculty of Medicine passed a very important resolution which provides that henceforth the holders of the posts of physician, surgeon and physician-accoucheur on hospital staffs shall be ineligible to hold professorships of anatomy, histology, physics, chemistry, and

died from meningitis, now only 25 per cent. of the fatal cases succumbed to that complication. The causes of death were now mostly either general sepsis or abscesses in the lung, liver, or spleen; formerly meningitis was chiefly responsible for the fatal results. Improved diagnosis of "otitic sepsis" or "pyæmia" would allow of earlier surgical intervention, so that the mortality might be still further reduced. Perhaps surgical treatment of otitic meningitis itself would be made possible. Several surgeons (Alexander, Neumann, and Körner) have tried, but have failed to find a satisfactory method for this purpose. Ligature of the jugular vein was an easy operation; a preparation of the vessel was made just as in the anatomical theatre and there was no shock whatever, because the nervous network surrounding the vessel was either injured or reduced in its vitality in consequence of the inflammation of the walls of the vessel. The fistula, leading from the skin to the vein, closed, if allowed to do so, in from eight to 14 days after the last particle of the thrombus had disappeared.

Successful Treatment of Lymphatic Leukæmia.

A few cases of successful treatment of lymphatic leukæmia are on record and the number has now been increased by that of a patient who was shown by Dr. Kienböck at a meeting of the Society for Internal Medicine in Vienna. The patient, a man aged 34 years, had been suffering for the past four years from swellings of the glands and increasing weakness. Two years ago an examination of the blood showed the presence of 5,000,000 red corpuscles and 165,000 leucocytes per cubic millimetre, whilst the hæmoglobin was only 16 per cent. The spleen reached a point five fingers' breadth below the costal arch. Systematic treatment by the x rays was applied in ten periods, each lasting from two to four weeks. The glands, the spleen, and the long bones of the extremities were exposed one after the other and each sitting lasted from 20 to 24 minutes. The immediate result of the application was the production of some toxic initial symptoms—namely, nausea and vomiting with an increase of temperature to 38° C. (101° F.). The leucocytes increased in number at first because they were being expelled into the vascular system, but after a few days they diminished considerably and rapid improvement followed, so that the patient was able to resume his occupation. The number of the red corpuscles has remained constantly between 4,000,000 and 4,250,000 and that of the leucocytes under 25,000 per cubic millimetre; the glands also required only every few months one or two exposures to the rays of a few minutes' duration. If the patient abstained from treatment for longer than four months the glands became visibly larger. The man was now practically as fit for work as he was five or six years ago. A quantitative estimate of the x rays, or rather of the electric energy, employed was made by means of strips of specially prepared paper which changed colour according to the amount of the rays acting on them. This was found to be the most convenient of the various colorimetric appliances because most of the others required a power of comparing colours which medical men did not always possess, whereas the paper strips showed different colours, not different shades of the same colour.

June 24th.

BUDAPEST.

(FROM OUR OWN CORRESPONDENT.)

Children and the Hygiene of Schools.

A WELL-KNOWN Hungarian journal devoted to subjects connected with the teaching profession has published a discussion on the relationship of physical, intellectual, and moral growth and development. In this article it is strongly urged that at whatever point in the educational system a boy has to stop in order to take up his life's work, up to that point his training should be broad and symmetrical; the training of the body should be recognised to be as important as that of the mind. The schoolroom should be large in proportion to the number of scholars, well lighted, and so arranged that the light enters on the left-hand side of the pupils as they are placed when writing. Good ventilation is important; the current of air should pass from inlets high up on the wall to outlets low down on the same wall. the temperature should be between 16° and 18° C. (62° and 67° F.) for the older children and 19° C. for the younger ones. The rooms should be heated by indirect radiation. In addition to the class-rooms the school building should have a gymnasium, with a swimming pool if possible. It is important to have sufficient ground around the school building for athletic sports; in towns the roofs can be used for playgrounds. In civilised communities the natural activities of the average child have little place, and therefore in order to obtain the best physical development which statistics showed to be essential to the highest intellectual growth it is necessary to make gymnastic exercises a part of the general curriculum. Exercise in general, and highly coördinated movements in particular, develop not only the muscles but the brain as well, and "team" games tend to raise the moral character. Bathing is of equal importance, for it stimulates the nervous system and not only prevents children from catching cold but acts as a cleansing agent. Over-fatigue must be guarded against, especially in children who are either anæmic or are growing rapidly, or are of a nervous disposition; girls entering on the adolescent period are very liable to be injured by over-fatigue. As signs of over-fatigue, awakening unrefreshed in the morning, inability to concentrate the attention, loss of memory, and irritability should be watched for and guarded against. Competitive examinations are important factors in causing over-fatigue and should be eliminated as far as possible by substituting marks depending on the daily work performed in the classes. The daily medical inspection of schools is a commendable feature of recent school management. On the intellectual side too much attention is given to certain "fads" and not enough to the fundamental studies. The class hours should be short, with the most difficult subjects in the morning. Optional studies should have no place in any grade below the latter part of the high-school course. In the higher grades hygiene and some knowledge of the processes of reproduction should be taught. Manual training is of great value in that it combines physical and mental training. Courses in domestic science are valuable adjuncts to the education of girls.

Modified Cow's Milk for Infant Feeding.

At the recent meeting of the Nagyvarad Medical Society Dr. Rácz Ödön read a paper on Cow's Milk for Infant Feeding. He said that in all attempts at the modification of cow's milk the fundamental considerations were: (1) to reduce the proportion of proteins by dilution; (2) to increase the quantity of fat, originally sufficient but reduced by the necessary dilution; (3) to increase the sugar and salt, likewise made deficient in amount by dilution; and (4) to sterilise or to pasteurise in warm weather and for special cases. Milk food ordered by prescription according to the percentage method and supplied by the laboratory has given him very excellent results, but he has obtained the same gratifying results from home modification by simple dilutions of "top" milk. For various reasons the modifications of cow's milk, whether made in the household or in the laboratory, would not give uniformly good results, no matter how accurate the adjustment of percentages might be. Cow's milk could not be converted into mother's milk by any treatment and it was necessary to use cow's milk as nature has furnished it. With proper hygienic management, however, clean cow's milk, properly diluted or modified, would suit the vast majority of bottle-fed infants provided that they were not overfed. The following simple method of home modification has been practised by Dr. Ödön who learned it from Dr. Caillè. If a quart bottle of average good milk was allowed to stand for four hours the upper half of the milk would contain about twice as much fat as the milk before standing. This portion of so-called top milk was decanted and formed the basis of bottle milk for home modification. By diluting this top milk in various proportions a product of various strengths as regards fat and proteins was obtained. The deficiency of salt and sugar was readily made up by the addition of these substances, and in this way a food was prepared which would vary in composition according to the requirements of the child to be fed. Printed directions for the feeding of infants of different ages could be had in any hospital. In a difficult case cow's milk should be discontinued for a short time and cereal decoctions and white of egg substituted. In resuming cow's milk a low strength should be used at first and should be gradually brought up to full strength milk, care being taken to avoid over-feeding. Digestion was best stimulated by carrying children out of doors and not by giving medicine. Peculiarities of pharmacology; holders of chairs must occupy themselves exclusively in teaching their special subjects.

June 24th.

ITALY.

(FROM OUR OWN CORRESPONDENT.)

Tuberculosis in the Mercantile Marine.

IN the combatant navy tuberculosis accounts for one-third of the death-rate. Judge what this must be in the mercantile marine, where the recruiting is much less strict and where the hygienic conditions are much less favourable. The Italian Hygienic Office is at present compiling statistics (which have hitherto been entirely wanting) of the death-rate from tuberculosis and other ailments in the mercantile marine, and the public, professional and lay, are awaiting them with an interest which is natural enough when the conditions are considered under which the "able-bodied seaman" is known to "live" if not to "thrive." He is, says a contributor to the columns of the leading Turinese journal, "a labourer inured to excessive fatigue, in an unwholesome atmosphere, the engine-men and the stokers under hatches being even worse off than their mates above them, though these latter have a very hard time of it, what with scanty and innutritious food and insufficient sleep." As for their "lodgement," continues the authority just quoted, no one who has inspected their sleeping accommodation can have failed to see that it offers every condition favourable to the development of tuberculosis, the cubic space reserved for air being quite below the normal standard and the air itself impure, not to say actively pernicious, while the dormitory itself is dark and damp. Add to this that the "lodgement" is often infected from the too facile admission on board ship of men suffering from tuberculosis, latent or even declared, while in cases where such subjects have been sent to hospital the dormitory which they have vacated is seldom, if ever, disinfected. In such conditions it will, indeed, be a marvel if the mortality from tuberculosis in the mercantile marine does not turn out to be greatly in excess of the mortality in the combatant service, all too high as that is.

The "Garibaldi Hospital."

Next week all Italy, indeed the whole Italian-speaking world, will be intent on the commemoration of the first centenary of the birth of Garibaldi and manifold will be the forms which that commemoration will assume. Among these will be the solemn dedication of the island-rock of Caprera as a national monument of the hero—the Government having purchased it for the nation; while another which would have proved even dearer to his heart will be the erection of a hospital for the poor at the adjacent Maddalena. In a letter now before me his son, General Ricciotti Garibaldi, writes: "Such an institution was greatly desired by my father, who, after having, by the aid of English friends, established at Maddalena and Ozieri free schools for the children of the poor, contemplated the building and equipment of a hospital for the sick and infirm of the same class. This project, actively taken up by my wife, has evoked the immediate sympathy and support of all. The ladies of the garrison and of the township of Maddalena have formed a committee *ad hoc;* the working men are devoting the proceeds of so many days' labour to the same end; and the town council has set apart the annual subsidy of 5000 francs (£200). Naturally the funds thus raised will not be enough, and the Government are memorialised to intervene with a special grant in aid. This hospital will prove a blessing to the people of Sardinia, particularly along the extensive seaboard of Gallura, where, for want of roads, the hospitals of Sassari and Tempio are practically closed to them." It is to be hoped that the response of the Premier and the Minister of Finance will be favourable to General Ricciotti Garibaldi's appeal.

June 22nd.

VIENNA.

(FROM OUR OWN CORRESPONDENT.)

University of Vienna.

AMONGST the officers of the University of Vienna who have been elected for the year 1907–08 the medical profession has many excellent representatives, and the highest position, that of the Rector Magnificus, has fallen to the lot of Professor Weichselbaum, the eminent pathologist. The rector must take part in all official proceedings, examinations, and promotions in the university. This position is not only the highest one which a professor can obtain during his career but it also involves the right to take part in the proceedings of the House of Lords as an active member, and the emoluments attached to it are considerable. Professor Paltauf, also a pathologist, was elected dean of the medical faculty for the coming academic year; his works on the status thymicus and the lymphatic constitution are widely known.

Roof Gardens for Hospitals.

Some hospitals which are now being erected, and others which are in contemplation, will be provided with roof gardens, so that the patients will be able to benefit by the excellent climatic conditions prevailing in Vienna during many months of the year. This old idea has been practically carried out long ago in Italy and also in America, where the high price of land has encouraged the laying out of this kind of recreation places. The new General Hospital, which will be given over to the medical faculty of the university in a short time, is now being adapted with a view to transform the roofs of nearly all the pavilions into "hanging gardens." The excellent position of the buildings—in a healthy level district sheltered from smoke and dust-laden winds and surrounded by private houses of no great height—will permit patients to spend much of their time on the top of the building amidst flowers and grass, in the open air. Lifts capable of conveying three or four beds at once lead on to the roof, where the beds will be wheeled to their places. It is also intended to let surgical patients have an abundant share of sunlight to act on their wounds. In connexion with this idea of utilising the house-tops, the municipal authorities have worked out a plan for erecting a hospital containing 1000 beds, where most of the chronic in-patients will be collected, especially those suffering from tuberculosis. These patients at present occupy many beds in the general hospitals and obstruct the admission of acute cases. The scarcity of hospital beds, so common in Vienna on account of the large percentage of tuberculous patients, will be easily done away with by the extra accommodation provided in this new large hospital. A sum of 10,000,000 kronen (£400,000) has been given by the municipality for this purpose to celebrate the jubilee of the Emperor who will in a few months complete the sixtieth year of his reign.

The Modern Treatment of Thrombosis of the Lateral Sinus.

Dr. Alexander at a recent meeting of the Gesellschaft der Aerzte read a paper on the results of the modern surgery of otitic pyæmia, especially as regards the treatment of thrombi in the sinus. His clinical material comprised 45 cases from the clinic of Professor Pollitzer. He emphasised the necessity of dealing with the jugular vein before the operation on the ear itself—namely, by the application of a double ligature, drainage of the diseased vessel towards the skin, and the radical removal of thrombotic masses. The thrombi in contact with the walls were more or less flat and their size varied from that of a small dot to a length of one or two inches. Very often they were an indication of circumscribed periphlebitis. The "thrombus obturans" was generally long, sausage-shaped, with pointed ends, and occluded the lumen entirely in its middle part only. The shape of the thrombus of the bulbus venæ jugularis corresponded with the shape of the latter, being globular. The centre of the thrombotic masses was generally soft and yellow, resembling pus. The ends were dark red, but there was hardly any difference between the ends and the centre as regards the infectious contents. The 45 cases were divided into two groups. The first group comprised 13 cases (up to the year 1903) when ligature of the jugular vein and drainage towards the skin were practised only optionally. Of these, nine (i.e., 69 per cent.) recovered and four (i.e., 31 per cent.) died, but only one of these deaths was due to meningitis. If compared with the results of other operators it was found that the latter had about the same mortality, but the cause of death was mostly meningitis. Of the remaining 32 cases, which were treated after 1903 with the invariable employment of double ligation of the jugular vein and drainage towards the skin, 80 per cent. recovered. This improvement was due undoubtedly to the improved technique and the removal of septic masses before perforating the bone. The results, as regards mortality, have been improved so far that whilst formerly 80 per cent. died, 80 per cent. now recovered, and whilst formerly 77 per cent.

died from meningitis, now only 25 per cent. of the fatal cases succumbed to that complication. The causes of death were now mostly either general sepsis or abscesses in the lung, liver, or spleen; formerly meningitis was chiefly responsible for the fatal results. Improved diagnosis of "otitic sepsis" or "pyæmia" would allow of earlier surgical intervention, so that the mortality might be still further reduced. Perhaps surgical treatment of otitic meningitis itself would be made possible. Several surgeons (Alexander, Neumann, and Körner) have tried, but have failed to find a satisfactory method for this purpose. Ligature of the jugular vein was an easy operation; a preparation of the vessel was made just as in the anatomical theatre and there was no shock whatever, because the nervous network surrounding the vessel was either injured or reduced in its vitality in consequence of the inflammation of the walls of the vessel. The fistula, leading from the skin to the vein, closed, if allowed to do so, in from eight to 14 days after the last particle of the thrombus had disappeared.

Successful Treatment of Lymphatic Leukæmia.

A few cases of successful treatment of lymphatic leukæmia are on record and the number has now been increased by that of a patient who was shown by Dr. Kienböck at a meeting of the Society for Internal Medicine in Vienna. The patient, a man aged 34 years, had been suffering for the last four years from swellings of the glands and increasing weakness. Two years ago an examination of the blood showed the presence of 5,000,000 red corpuscles and 185,000 leucocytes per cubic millimetre, whilst the hæmoglobin was only 16 per cent. The spleen reached a point five fingers' breadth below the costal arch. Systematic treatment by the x rays was applied in ten periods, each lasting from two to four weeks. The glands, the spleen, and the long bones of the extremities were exposed one after the other and each sitting lasted from 20 to 24 minutes. The immediate result of the application was the production of some toxic initial symptoms—namely, nausea and vomiting with an increase of temperature to 38° C. (101° F.). The leucocytes increased in number at first because they were being expelled into the vascular system, but after a few days they diminished considerably and rapid improvement followed, so that the patient was able to resume his occupation. The number of the red corpuscles has remained constantly between 4,000,000 and 4,250,000 and that of the leucocytes under 25,000 per cubic millimetre; the glands also required only every few months one or two exposures to the rays of a few minutes' duration. If the patient abstained from treatment for longer than four months the glands became visibly larger. The man was now practically as fit for work as he was five or six years ago. A quantitative estimate of the x rays, or rather of the electric energy, employed was made by means of strips of specially prepared paper which changed colour according to the amount of the rays acting on them. This was found to be the most convenient of the various colorimetric appliances because most of the others required a power of comparing colours which medical men did not always possess, whereas the paper strips showed different colours, not different shades of the same colour.

BUDAPEST.

(FROM OUR OWN CORRESPONDENT.)

Children and the Hygiene of Schools.

A WELL-KNOWN Hungarian journal devoted to subjects connected with the teaching profession has published a discussion on the relationship of physical, intellectual, and moral growth and development. In this article it is strongly urged that at whatever point in the educational system a boy has to stop in order to take up his life's work, up to that point his training should be broad and symmetrical; the training of the body should be recognised to be as important as that of the mind. The schoolroom should be large in proportion to the number of scholars, well lighted, and so arranged that the light enters on the left-hand side of the pupils as they are placed when writing. Good ventilation is important; the current of air should pass from inlets high up on the wall to outlets low down on the same wall. The temperature should be between 16° and 18° C. (62° and 67° F.) for the older children and 19° C. for the younger ones. The rooms should be heated by indirect radiation. In addition to the class-rooms the school building should have a gymnasium, with a swimming pool if possible. It is important to have sufficient ground around the school building for athletic sports; in towns the roofs can be used for playgrounds. In civilised communities the natural activities of the average child have little place, and therefore in order to obtain the best physical development which statistics showed to be essential to the highest intellectual growth it is necessary to make gymnastic exercises a part of the general curriculum. Exercise in general, and highly coördinated movements in particular, develop not only the muscles but the brain as well, and "team" games tend to raise the moral character. Bathing is of equal importance, for it stimulates the nervous system and not only prevents children from catching cold but acts as a cleansing agent. Over-fatigue must be guarded against, especially in children who are either anæmic or are growing rapidly, or are of a nervous disposition; girls entering on the adolescent period are very liable to be injured by over-fatigue. As signs of over-fatigue, awakening unrefreshed in the morning, inability to concentrate the attention, loss of memory, and irritability should be watched for and guarded against. Competitive examinations are important factors in causing over-fatigue and should be eliminated as far as possible by substituting marks depending on the daily work performed in the classes. The daily medical inspection of schools is a commendable feature of recent school management. On the intellectual side too much attention is given to certain "fads" and not enough to the fundamental studies. The class hours should be short, with the most difficult subjects in the morning. Optional studies should have no place in any grade below the latter part of the high-school course. In the higher grades hygiene and some knowledge of the processes of reproduction should be taught. Manual training is of great value in that it combines physical and mental training. Courses in domestic science are valuable adjuncts to the education of girls.

Modified Cow's Milk for Infant Feeding.

At the recent meeting of the Nagyvarad Medical Society Dr. Rácz Ödön read a paper on Cow's Milk for Infant Feeding. He said that in all attempts at the modification of cow's milk the fundamental considerations were: (1) to reduce the proportion of proteins by dilution; (2) to increase the quantity of fat, originally sufficient but reduced by the necessary dilution; (3) to increase the sugar and salt, likewise made deficient in amount by dilution; and (4) to sterilise or to pasteurise in warm weather and for special cases. Milk food ordered by prescription according to the percentage method and supplied by the laboratory has given him very excellent results, but he has obtained the same gratifying results from home modification by simple dilutions of "top" milk. For various reasons the modifications of cow's milk, whether made in the household or in the laboratory, would not give uniformly good results, no matter how accurate the adjustment of percentages might be. Cow's milk could not be converted into mother's milk by any treatment and it was necessary to use cow's milk as nature has furnished it. With proper hygienic management, however, clean cow's milk, properly diluted or modified, would suit the vast majority of bottle-fed infants provided that they were not overfed. The following simple method of home modification has been practised by Dr. Ödön who learned it from Dr. Caillé. If a quart bottle of average good milk was allowed to stand for four hours the upper half of the milk would contain about twice as much fat as the milk before standing. This portion of so-called top milk was decanted and formed the basis of bottle milk for home modification. By diluting this top milk in various proportions a product of various strengths as regards fat and proteins was obtained. The deficiency of salt and sugar was readily made up by the addition of these substances, and in this way a food was prepared which would vary in composition according to the requirements of the child to be fed. Printed directions for the feeding of infants of different ages could be had in any hospital. In a difficult case cow's milk should be discontinued for a short time and cereal decoctions and white of egg substituted. In resuming cow's milk a low strength should be used at first and should be gradually brought up to full strength milk, care being taken to avoid over-feeding. Digestion was best stimulated by carrying children out of doors and not by giving medicine. Peculiarities of idiosyncrasy with regard to cow's milk in proper dilution should not be suspected until after the child has had proper hygienic management. Infants and children who were kept indoors in cool and cold weather and compelled to breathe the air of overheated and stuffy apartments would not digest their food well, no matter what they were fed on. In cases of peculiar idiosyncrasy with regard to cow's milk a substitute must be found and this should, if possible, be the breast of a wet-nurse. In some cases whey with cream and some cereal decoction would answer.

CANADA.

(FROM OUR OWN CORRESPONDENT.)

Ontario Medical Association: Annual Meeting.

THE twenty-seventh annual meeting of the Ontario Medical Association was held in Toronto on May 28th, 29th, and 30th, under the presidency of Dr. George A. Bingham (Toronto), Dr. Charles P. Lusk (Toronto) acting as secretary. It proved to be the second largest meeting in the history of the organisation. The address in medicine was delivered by Dr. Mazyck P. Ravenal of the Phipps Institute, Philadelphia, who took for his subject Methods of Infection in Pulmonary Tuberculosis. Dr. A. J. Richer of the St. Agathe Sanatorium, province of Quebec, followed this with a paper on Immune Therapy in Tuberculosis. In it he considered that the use of tuberculin had been proved to be advantageous in cases which had not passed into the incurable class, whilst in apparently healthy subjects it had the advantage of giving immunity or revealing latent disease. The address in surgery was delivered by Dr. George W. Crile, of Cleveland, U.S.A., the subject being Clinical and Experimental Observations on the Direct Transfusion of Blood. During the progress of the meeting there were held two very important and interesting symposia. The first of these was on the Profession in Relation to the Public. This brought out papers by Dr. G. Silverthorn (Toronto) on the Medico-legal Aspects; by Dr. J. W. S. McCullough (Alliston) on the Public Health Aspects; by Dr. C. K. Clarke (Toronto) on Ideals for Asylum Work in Ontario; and by Dr. J. A. Amyot on the Infection of Drinking Water. In connexion with the medico-legal aspects of this discussion Dr. D. D. MacTaggart (Montreal) advocated that all coroners should be legal men and that these inquiries should be conducted by them; with them should be associated a medical man. He also advocated the organisation of a medico-legal society for Canada. The reader of the paper on the Public Health Aspects of the Relation of the Profession of Medicine to the Public advocated a fair remuneration for medical health officers, fees for the registration of births and infectious diseases, as well as a fee for issuing burial or death certificates. Resulting from this discussion the committee on public health was empowered by the association to take such steps as were deemed advisable to get appointed county medical health officers throughout the Province. Dr. C. K Clarke, superintendent of the Toronto provincial Hospital for the Insane, made the announcement that the Ontario Government would shortly establish in Toronto a Government hospital clinic for psychiatry. Dr. T. J. W. Burgess (Montreal), superintendent of the Protestant Hospital for the Insane at Verdun, province of Quebec, denounced the practice of appointing politicians to the heads of these institutions and passing over the assistants who had been trained for years in their work. No junior should be appointed unless he showed a penchant for the work, and the time would come when no general practitioner would dare to accept the superintendency of one of these special hospitals. The other symposium was on the Treatment of Fractures. Dr. D. E. Mundell (Kingston, Ontario) led off with a paper on Fractures of the Skull; Dr. F. N. G. Starr (Toronto) followed with Fractures near the Elbow; Fractures near the Wrist and Ankle was dealt with by Dr. A. W. Brighton (Ontario); and Dr. W. E. Gallie (Toronto) closed the symposium with a paper on Fractures of the Femur. The Association decided to meet next year in Hamilton, Ontario, with Dr. Ingersoll Olmsted of that city as President, Dr. C. P. Lusk (Toronto) as secretary, and Dr. F. Fenton (Toronto) as treasurer.

Physician Fined for Failing to make a Call.

A medical man of Montreal recently appeared before the Recorder's court on the complaint set forth that he ha failed to register within 24 hours the death of a child wh had died from typhoid fever. He denied the indictment, a he had visited the child only once, and alleged that he ha not been informed of the patient's death. It appea that the child died on a Sunday and the medical ma had not been in the habit of paying visits on th day. The judge held, however, that it was his duty a a medical man to have visited the child on the Sunda in question, because when he had visited the patient he mu have been fully aware of the seriousness of the illne In delivering his judgment the learned justice stated that th duties of a medical man had to be performed at all hours i the same manner as those of a priest or minister. In thi instance he held that the accused had failed to perform hi duty which was to have ascertained whether his littl patient was alive or not. He therefore ordered the accuse to undergo a fine of $20 or an alternative of one month' imprisonment.

Western Hospital, Montreal.

A new Western Hospital building is about to be opene in Montreal. The first building of this rapidly growing an progressive institution was erected in 1872, 35 years ag For about 20 years it was used for a special hospital whe it was changed to a public general hospital. At first th management found it an uphill task and for several yea the collections were deficient and debt accumulated. The a new management came to the fore and soon the debt wa discharged and a successful balance-sheet was shown. Th medical board is composed of many of the best surgeon and physicians in Montreal. The new building will hav an additional accommodation for 100 beds, including 2 private wards. It has cost $75,000, and the committee o management has undertaken to raise a special fund o $100,000 for hospital purposes. Already about one-third o this amount is in sight The private ward department wil supply a want sufficiently urgent at the present time i Montreal as all the large hospitals have these wards alway occupied. That department will always be self-sustaining.

June 17th.

AUSTRALIA.

(FROM OUR OWN CORRESPONDENT.)

The Plague.

A CASE of bubonic plague has at last been discovered i Melbourne but the patient was infected in Sydney, he being a steward on one of the coastal steamers. He felt ill o leaving Sydney and immediately on arriving at Melbourne went to the hospital, when bacteriological examination of the serum from the inguinal bubo, for which he sought treatment, proved the case to be one of plague. He has been isolated in the plague hospital at Cook Island. The steamer has been thoroughly disinfected and the crew isolated. Cases continue to be reported from Sydney. One fatal case occurred on May 12th. During the present outbreak 42 cases have been notified, 13 of which were fatal. Plague infected rats are still being caught both in Sydney and Brisbane.

Proposed Institute for Tropical Diseases.

The chairman of the Townsville Chamber of Commerce and the medical superintendent of the Townsville Hospital recently waited on the Minister for Home Affairs of the Commonwealth and placed before him the proposal to establish an institute for the observation of tropical diseases. It was estimated that the maintenance of the institute would cost about £700 a year. The Queensland Government was expected to contribute £250 and the Commonwealth Government was asked to vote £250 also and to divert to the institute the sum of £200 already appropriated for investigation of tropical diseases abroad. The Minister promised to recommend the Cabinet to grant the request for the extra £250 a year, but as he was not aware of the conditions under which the £200 already voted was being expended he could say nothing in regard to it until inquiry had been made. The Faculty of Medicine of Melbourne has passed the following resolution on the subject:—

> That the Faculty of Medicine strongly approves of the foundation of an institute of tropical medicine on the general lines suggested by the Bishop of North Queensland and is of opinion that economy and efficiency will both be promoted by the organic connexion of the institute with the Universities of Sydney, Melbourne, and Adelaide, and by full use of the existing University laboratories.

Dr. Danysz's Experiments on the Destruction of Rabbits.

Dr. Danysz has submitted a report on the bacteriological experiments conducted at Broughton Island from October, 906, to May, 1907. As a result he affirms: first, the Pasteurellosis of the rabbit is a disease which can transmit itself from the diseased to the healthy during the life of the diseased; secondly, the spots where the infected rabbits have lived and died remain infectious for a certain time. On the island, infection of the lungs and nose, the most frequent form, as well as the most contagious, of Pasteurellosis of rabbits in Europe has not occurred, presumably owing to special climatic conditions. Dr. Danysz is sanguine that the same conditions would not obtain on the mainland, and that then the disease would prove more contagious. The experiments showed that an experimentally infected rabbit would infect about three healthy rabbits. As to infection to other animals, the experiments showed that the virus is dangerous to rabbits only. In his retiring address as president of the Royal Society of New South Wales Professor Anderson Stuart referred to the subject of the destruction of rabbits and pointed out that even if a suitable virus for killing rabbits were obtained it could not be hoped that rabbits in the open could be exterminated thereby. Being parasites, if the microbes killed the animals on which they lived they could not survive to infect others. Thus the plague microbe infected rats, but unfortunately did not exterminate them.

Health of Victoria.

Statistics presented to the Board of Public Health of Victoria for the fortnight ending May 5th show that the State continues much more free from typhoid fever than in former years. The number of cases reported was 58, with three deaths, as against an average of 131 cases and eight deaths for similar periods in the last four years. The returns for scarlet fever show only 12 cases with no deaths, as against an average of 105 cases with one death. A slight increase occurred in diphtheria, 73 cases with two deaths, as against an average of 60 cases with two deaths.

Public Health Administration in Victoria.

The chairman of the Board of Public Health of Victoria (Dr. Norris) has furnished the Board with a memorandum on sanitary administration. After reviewing the history of legislation in the State relating to public health he observes that the Board's powers of enforcing its directions to municipal councils which act as local boards of health "are cumbersome, tardy, and ineffective." He holds that a great deal of the present inefficiency in health administration is due to the system of appointing health officers, and strongly advocates groups of municipalities acting jointly to appoint specially qualified officers of health whose whole time would be given to the study of the sanitary needs of their districts and to keeping the councils continuously furnished with fuller information and a clearer view of the sanitary defects, affording them no excuse for inaction and stimulating them to exercise the powers which they possess. At the same time the controlling and coercive powers of the Board should be strengthened. A certain portion of municipal subsidies should be payable only on a certificate of the Board that primary sanitary requirements have been observed by the councils the functions and responsibilities of which should not be curtailed in any way.

Medical Inspection of Schools in New South Wales.

Dr. Roth has been appointed medical officer to the Department of Public Instruction in New South Wales. He will make an annual inspection of all the schools of the capital and suburbs and will report as to the hygienic conditions of school premises, and recommend what is necessary to remedy any defects in school buildings likely to be detrimental to the health of the scholars. He will also examine children who appear to be suffering from any complaint likely to interfere with the progress of their education, and the parents will be notified of such cases and advised where necessary to obtain proper treatment. He will ascertain if any of the children are physically unfit for ordinary physical school exercises. Sight-testing will also come within the scope of his duties. Anthropometric data will be obtained by the teachers with regard to the height and weight of scholars of different ages.

May [illegible]th.

AT the last general meeting of the Balneological and Climatological Society Dr. W. J. Tyson (Folkestone) was elected President of the society for the ensuing year.

Obituary.

JULIUS DRESCHFELD, M.D. WÜRZB., F.R.C.P. LOND., B.SC. VICT.

THE medical profession in Manchester has suffered heavily of late in the loss, by the hand of death, of many of its well-known members. Of those taken none will be more missed and more regretted than the subject of this notice. Born at Niederwerm in Bavaria Dr. Dreschfeld received his early education at Bamberg. He went to Manchester, however, in 1861, when he was about 16 years of age, and from that time, with the exception of a comparatively short interval, he made that city his home. He at once became a student at the Owens College, the initial stage in the evolution of the Victoria University, and soon showed that he possessed not only great ability but also the will and the power to use it. As a nation we are supposed to be less capable of acquiring languages than most others, but though young Dreschfeld came of a race remarkable for linguistic aptitude he must have had determination as well as readiness to enable him, though so short a time in this country, to win the first prize in the English class. This was not his only trophy, for he took prizes in the class examinations in several subjects, including mathematics and science. In 1863 he gained the Dalton chemical prize with an essay on the Chemical and Physical Properties of Water and the year following the Dalton junior mathematical scholarship. His early medical education was commenced at the Manchester Royal School of Medicine, afterwards connected with the Owens College and now a department of the Victoria University. In 1864 he returned to Bavaria and studied medicine at Würzburg, where he took the degree of M.D. in 1867, and for a time was assistant to von Bezold, the professor of physiology. But before taking his degree he served in 1866 in the Bavarian army as an assistant surgeon during the Austro-Prussian war. Three years later (in 1869) he returned to England, took the diploma of L.R.C.P. Lond., and began practice in Manchester. In 1872 he was appointed honorary physician to the Hulme dispensary and soon afterwards became one of the assistant physicians to the Manchester Royal Infirmary. In 1683 he was elected full physician on the resignation of Sir William Roberts, and his active association with the infirmary lasted till 1905, when the age-limit of 60 years deprived that institution of his more immediate services, and he was appointed consulting physician, a distinction which he only enjoyed for about two years. In 1875 Dr. Dreschfeld passed the examination for the Membership of the Royal College of Physicians of London and in 1683 was elected a Fellow, and five years later (in 1888) was appointed Bradshaw lecturer at the College when he delivered an important address on Diabetic Coma. At a later period he was an examiner for three years for the Royal College of Physicians of London and for a period of four years he was examiner in medicine at the University of Cambridge. Early in his Manchester career Dr. Dreschfeld paid great attention to morbid anatomy and histology, and in 1875 he was asked by the council of the Owens College to supervise the pathological section of the medical museum and to classify and to catalogue the specimens. He was also appointed lecturer on pathology at the Owens College and in 1831 the position was raised to the dignity of a professorship, which he held until 1891, when he became professor of medicine to the College—an appointment which he held till his death. Soon after he became lecturer on pathology he organised a pathological laboratory, perhaps the first, or at all events one of the first, in this country. It is said that the number of students attending Dr. Dreschfeld's classes increased from three in 1870 to 110 in 1891. In that year the late Dr. John Edward Morgan resigned the professorship of medicine to which Dr. Dreschfeld was elected, and this position he occupied till his death. His lectures were clear, concise, and complete and were thoroughly appreciated by the students. A man of Dr. Dreschfeld's powers could not fail to influence the members of his profession in Manchester, for he took a warm and active interest in the various societies connected with both the scientific and the practical side of medicine. There was for a long time a microscopical section of the Medical Society, which he helped to convert into the Pathological Society, Dr. H. Ashby being its first president. Dr. Dreschfeld, who succeeded him, was also a very regular attendant at the meetings of the Medical Society itself and its president in 1888. The mother and daughter societies, it may be noted, are friendly and complementary to each other. Another society which may be said to have sprung from the senior one is the Manchester Therapeutical Society, of which also Dr. Dreschfeld was a president. His contributions to these societies were numerous and valuable. In addition to the physicianship of the infirmary he was consulting physician to the Skin Hospital, to the Society for Aiding Distressed Foreigners, and honorary physician to the Christie Cancer Hospital and Home, and quite recently he accepted the honorary physicianship to the Manchester Victoria Jewish Hospital, to the great satisfaction of its supporters. For 15 years he was a member of the English committee of the International Medical Congress and in 1902 was President of the Section of Medicine at the Manchester meeting of the British Medical Association. Dr. Dreschfeld's contributions to the literature of medicine were numerous, on many subjects, and of high value. From "the seventies" to the close of his life there was an almost uninterrupted succession of weighty articles by him in Clifford Allbutt's "System of Medicine," in the *Journal of Anatomy and Physiology*, in *Brain*, in the *Medical Chronicle*, and in other journals. It is sad to think that he will not, as he had consented to do, give the Lumleian lectures next year.

Perhaps few men have been more devoted, or have given a more whole-hearted allegiance to their profession than did Dr. Dreschfeld, and as a consequence he was not able to find time for public work. His interest in what was going in city and State was, however, active, and, a lover of music, he was for many years a constant attendant at the Hallé concerts. Dr. Dreschfeld was twice married. His first wife left four children, two sons and two daughters, and in 1905 he married the daughter of the late Dr. Lilley of Leamington. In these days, 62 is accounted an early age at which to be cut off, but Dr. Dreschfeld had done a long life's work. Though for some years he had been much troubled with rheumatism his health was fairly good; he had, however, complained of not feeling well since Whitsuntide last. His death on June 15th was unexpected and he had only taken to his bed four days previously. He was a man characterised by genial and pleasant manners and genuine kindness of heart, and the blank left by his death will be sorely felt for a long time to come. He was buried at Southport and the funeral was attended by many of his old friends and colleagues.

Medical News.

Society of Apothecaries of London.—At examinations held in June the following candidates passed in the subjects indicated:—

Surgery.—M. L. Ford (Section I.) and S. F. Fouracre (Section II.) Charing Cross Hospital; and C. C. H. L. Moll (Section I.), Guy's Hospital.

Forensic Medicine.—P. D. Pickles and G. L. Walker, Leeds.

Midwifery.—J. M. Murray, Royal Free Hospital and Durham; and A. Sheppard, Guy's Hospital.

The diploma of the Society was granted to the following candidates entitling them to practise medicine, surgery, and midwifery:—S. F. Fouracre, A. Sheppard, and G. L. Walker.

University of Cambridge.—At a special Congregation for honorary degrees held on June 12th the public orator presented Sir Thomas R. Fraser for the degree of D.Sc. with these words, in the delivery of which he adopted the reformed Latin pronunciation:—

> In Uniuersitate Edinensi iam per annos triginta materiam medicam est professus uir in remediorum ui et usu inuestigando iamdudum exercitatus. *Abhinc annos* plus quam quadraginta de magica illa faba, physostigmate uenenoso, disputauit, et propterea Francogallorum ab Instituto laurea insigni est coronatus. Quid dicam de pestilentia illa per Indiam quondam grassante, ab hoc uiro per triennium audacter inuestigata? Quid de serpentium ueneno ab eodem fortiter *explorato?* Quid de atropia et strophantho? In medicina etiam uenena nonnumquam prodesse ne antiquis quidem prorsus ignotum. Talium autem uirorum auxilio disciplina illa, "quondam paucarum scientia herbarum," "in hanc peruenit tam multiplicem uarietatem."
>
> Duco ad uos medicinae professorem illustrem Edinensem, equitem insignem, Thomam Richardum Fraser.

At the final Congregation of the academical year held June 18th the following degrees were conferred:—

M.B. and B.C.—J. A. Venning, Trinity; P. A. Lloyd-Jo and H. Hardwick-Smith, St. John's; S. L. Harke, Pembro A. E. Kerr, Christ's; C. W. Greene, Emmanuel; and H. A. R. Unwin, Host. Selwyn.

M.B.—A. B. Wilson, Pembroke; R. G. Markham and G. L. We Caius; T. S. Hele, Emmanuel; and A. N. Dickson, Downing.

B.C.—C. Tylor, Caius.

During the academical year 28 Doctors of Medicine, to Masters of *Surgery, 56 Bachelors of Medicine*, and Bachelors of Surgery have taken their degrees in t University.

At examinations for medical and surgical degrees, Eas term, the following candidates were successful:—

First Examination.

Part I., Chemistry and Physics.—W. B. Alcock, Trinity Hall; Arnfield and L. W. Barlow, Caius; W. F. Bensted-Smith, Pe broke; A. H. Birks, Caius; J. Brewer and D. F. Burton, Emmanu E. Calvert and C. G. H. Campbell, St. John's; M. H. Cane, King J. W. H. Chun, Trinity; J. D. Clarke, Sidney Sussex; L. B. Cla and A. C. Clifford, Emmanuel; G. B. Code, Pembroke; E. R. Cooke, Emmanuel; J. H. Cumming, Pembroke; G. C. F Sidney Sussex; A. N. Garrod, Emmanuel; B. Graves, Chri J. L. Green and E. F. W. Grellier, Downing; A. F. Hall, St. Jo J. D. Jones, H. Selwyn; A. Kennedy, Caius; C. H. Leeke, J. D. Legge-Currie, Clare; G. R. D. McGeagh, Caius; W. C Malle, Pembroke; A. S. L. Malcolm, Caius; R. K. Emmanuel; G. C. Metcalfe and E. J. Nangle, Caius; W. S. N. Clare, Clare; A. B. Paul, Christ's; N. P. Pritchard and L. C. Bl Trinity; R. S. Scott, Caius; H. J. S. Shields, Jesus; J. W. S and C. R. Taylor, Caius; H. F. W. Warden and C. Warner, Pe broke; H. A. Watermeyer, Caius; and B. H. C. Wilson, Trinity.

Part II., Elementary Biology.—W. B. Alcock, Trinity Hall; L. A. Anderson, Emmanuel; G. Arnfield and L. W. Barlow, Caius; W. Bensted-Smith, Pembroke; A. V. Boyall, Trinity; J. Brewer D. F. Burton, Emmanuel; E. Calvert, St. John's; J. W. H. Ch Trinity; J. D. Clarke, Sidney Sussex; A. C. Clifford, Emmanu B. K. T. Collins, Trinity; A. G. W. Compton, B.A., Caius; S. Crosse, Pembroke; J. Deighton, Trinity; E. L. Dobson, King's; Donaldson, Trinity; G. C. Fairchild, Sidney Sussex; A. N. Garr Emmanuel; J. E. Gething, B.A., Pembroke; B. Graves, Christ J. L. Green and E. F. W. Grellier, Downing; R. H. Growse, Cai A. F. Hall, St. John's; S. M. Hattersley, Emmanuel; D. W. Jo Clare; I. W. Joynt, Emmanuel; G. R. D. McGeagh, Caius; J. M. Mackenzie, Trinity; Q. Madge, Emmanuel; W. C. D. Malle, Pe broke; A. S. L. Malcolm, Caius; E. G. Martin, B.A., Trinity Ha R. K. Merson, Emmanuel; G. C. Metcalfe and E. J. Nangle, Caiu W. S. Newton-Clare, Clare; N. F. Norman, Downing; T. Ow Jesus; A. B. Paul, Christ's; J. H. Pendered, Caius; D. Pickering, Emmanuel; A. C. Pickett, Caius; L. C. Rive Trinity; L. T. Rutherford, Clare; R. S. Scott, Caius; Sharpe, B.A., Pembroke; L. W. Shelley, Caius; H. J. Shields, Jesus; F. B. Smith, King's; G. A. Smythe, Emmanu L. C. Somervell, King's; J. W. Stretton, Caius; A. L. Sutclif Sidney Sussex; C. R. Taylor, Caius; J. F. Taylor, H. Selwy G. S. E. Thomas, Downing; J. W. Tonks, Caius; G. A. Wa Queen's; J. R. Waddy, H. F. W. Warden, and C. Warner, Pe broke; W. G. Watson, Caius; and S. M. Wilcox, Emmanuel.

Second Examination.

Human Anatomy and Physiology.—W. A. Anderson, B.A., Clar E. W. Atkinson, B.A., Caius; H. J. Baldwin, M.A., Emmanu A. W. Bourne, Downing; J. S. Burn, B.A., Trinity; F. Chandler, Jesus; N. L. Clarke, Christ's; K. J. A. Davis, B. King's; M. E. Dellschaft, Jesus; R. Gamlin, B.A., King E. St. G. S. Goodwin and A. H. Gosse, B.A., Caius; H. Greaves, B.A., Emmanuel; S. J. Higgins, B.A., Caius; J. Jarvie, B.A., Emmanuel; J. S. Jobson, B.A., Sidney Sussex; A. Johnson, Downing; G. G. Johnstone, King's; T. H. Just, Trinit K. T. Khong, St. John's; G. Moore, Clare; T. E. Osmond, B. Emmanuel; W. M. Penny, B.A., Jesus; B. A. Playne, Pembrok G. H. Pooley, Caius; J. B. Pulling, Christ's; A. H. Richard and J. B. Ronaldson, B.A., St. John's; S. H. Rouquette, King A. C. Roxburgh, Trinity; H. B. G. Russell, Sidney Sussex; F. Saner, Christ's, L. W. K. Scargill, M.A., Trinity Hall; F. H. Smit B.A., Christ's; A. W. Stott, Trinity; J. Van Schalkwijk, B. Caius; H. F. Wilson, Christ's; and M. M. Woods, Clare.

Third Examination.

Part I., Pharmacology and General Pathology.—C. W. Archer, B.A Trinity; A. E. Bonny, Sidney Sussex; R. S. Carey, B.A., Corp Christi; L. Colledge, B.A., Caius; C. A. Dottridge, B.A., Cla E. A. Dyson, B.A., Jesus; A. Feiling, B.A., Pembroke; P. Gilroy, B.A., H. Selwyn; A. H. Habgood, B.A., Jesus; A. Hargreaves, B.A., Trinity; S. L. Harke, B.A., Pembrok W. Harmens, B.A., Trinity; E. H. V. Hodge, B.A., Clare; H. Humphrys, B.A., Caius; R. H. Hutchinson, B.A., Clare; P. C. Jones, B.A., St. John's; G. O. Kidd, B.A., Christ's; F. H. Lest B.A., Pembroke; P. A. Lloyd-Jones, B.A., St. John's; C. McKerrow, B.A., Clare; L. Meakin, B.A., Trinity; A. F. Morco B.A., Clare; L. B. Perry, B.A., Queen's; J. H. Ryffel, M.A., Pete house; R. M. R. Thursfield, B.A., H. Selwyn; J. H. Trench, B.A Trinity; C. Tylor, B.A., Caius; R. M. Vick, B.A., Jesus; B. Webb Non Collegiate; T. N. Wood, B.A., Pembroke; and A. E. M. Woo B.A., and C. S. E. Wright, B.A., Emmanuel.

Part II., Surgery, Midwifery, and Medicine.—F. O. Arnold, B.A and P. H. Bahr, B.A., Trinity; G. D. Bartlett, B.A., Sidne Sussex; H. Beckton, M.A., Clare; R. Burgess, B.A., and S. Chan, B.A., Caius; S. Churchill, B.A. Trinity; A. I. Cooke, B.A Caius; A. T. Densham, B.A., St. John's; A. N. Dickson, Downin H. Dimock, B.A., Sidney Sussex; C. W. Greene, B.A., Emmanuel G. F. Greenwood, B.A., Sidney Sussex; C. L. M. Jones, B.A King's; A. R. Jordan, B.A., Clare; B. T. Lang, B.A., Trinity R. B. Lloyd, B.A., Emmanuel; L. H. L. Mackenzie, B.A., Trinity

R. G. Markham, B.A., and H. F. Marris, M.A., Caius; J. H. B. Martin, B.A., *Emmanuel; L. Nicholls, B.A., Downing;* C. W. Ponder, M.A., Emmanuel; *J. H. Pratt, B.A., Trinity;* C. L. Scarborough, M.A., St. John's; A. L. Singer, B.A., King's; E. F. Skinner, M.A., Corpus Christi; A. C. H. Suhr, B.A., Caius; C. B. Ticehurst, B.A., St. John's; C. Tylor, B.A., Caius; J. A. Venning, B.A., Trinity; *B. Wahby, Non Collegiate; R. R. Walker, B.A.,* St. John's; A. B. Wilson, B.A., Pembroke; and R. F. Young, B.A., Christ's.

UNIVERSITY OF OXFORD AND PROFESSOR EHRLICH.—The following is the text of the Latin speech in which Professor Love introduced Professor Ehrlich for the honorary degree of D.Sc. :—

Antiquis ea erat *medendi ratio* ut *angores levarent vel varia* molestiarum genera minuerent *medicamentis* vel quæ affectus contrarios excitarent: recentes id propositum habent ut abdita morborum semina iam inolescentia et in vivis medullis concreta deprehendant et exstinguant. Ita non solum *morbo* quo quisque laboret *mederi sed ipsum corpus quasi præsidiis occupare* et inexpugnabile facere conantur. In maximo hoc bello quod hodie geritur contra febres varias, velut *διφθεριαν* quam vocant, contra cancros, vel malis seminibus vel ipsius carnis corruptione ortos, nemo melius vel iam munivit vel in acie præliatus est quam Paulus Ehrlich. Victoria quidem nondum reportata est: quamvis multi hostes fusi sint, restant illi mox superandi: huic certe viro summa diligentia et prudentia, erudito, salubritatis *patrono* et *præsidi, siquid bene gestum est* acceptum *referre* debemus: huius opera et eorum qui sub eius signis militant novos triumphos reportari posse speramus.

TRINITY COLLEGE, DUBLIN.—At examinations held in Trinity term the following candidates were successful:—

Diploma in Public Health, Part II.—Cecil Scaife.

Final Medical Examination, Part II., Medicine.—William Pearson (passed on high marks), Richard G. S. Gregg, Robert E. Wright, William A. R. Spong, Henry de C. Dillon, James G. M. Moloney, William E. M. Armstrong, Wilfrid J. Dunn, Thomas P. S. Eves, Henry P. Hart, Frederick Stevenson, Francis O'B. Kennedy, James D. K. Roche, Oliver St. J. Gogarty, James C. C. Hogan, Charles H. O'Rorke, Ernest T. Jameson, Joseph C. A. Ridgway, Edmond H. Sheehan, James R. Yourell, Archibald L. Robinson, and Wallace D. Mitchell.

THE GRAND PRIORY OF THE ORDER OF ST. JOHN OF JERUSALEM IN ENGLAND.—The annual commemoration service of the Grand Priory of the Ordar *of* the Hospital of St. John of Jerusalem in England was held in St. John's parish church, Clerkenwell, on June 24th. The sermon was preached by the Rev. T. O. Elsdon, who said that the Order was founded at Jerusalem in 1092. It now assisted suffering humanity all *over* the Empire and the new charter would enable the work to be extended. *After* the service a general assembly of the Order was held in the council room at St. John's Gate.

OPHTHALMOLOGY AND THE UNIVERSITY OF OXFORD.—The fourth annual course on ophthalmology will be held from July 15th to 27th. The main idea of the *course* is to demonstrate (on actual patients so far as possible) the whole range of ophthalmology. The first portion of the course will be mainly devoted to demonstrating the practical examination of eye patients, the use of the ophthalmoscope, and the work of refraction. During the second portion the work will be more specialised. Altogether some 500 cases will be present for demonstration. The course will be illustrated by the *lantern* and the fee for the course is £5 5*s.* Gentlemen attending the course will be provided with board and residence at *Keble College* at the rate of 7*s.* 6*d.* a day. For further particulars application should be made to *Mr. Robert W. Doyne,* Margaret Ogilvie's reader in ophthalmology in the University of Oxford, 30, Cavendish-square, London, W. Between 80 and 90 surgeons accepted the invitation given last year to see some of the more interesting cases collected for the post-graduate course of ophthalmology at Oxford and other demonstrations. The apparent appreciation of those who came has encouraged the idea of another gathering of the same sort this year on July 26th and 27th. In order that it may not clash with the meeting of the British Medical Association in the *following* week a series of demonstrations, rather than papers and discussions, has been arranged. Mr. E. Nettleship, who will preside over the meeting, will give an address, and demonstrations by both British and foreign physicists, physiologists, and ophthalmologists have been arranged. Moreover, *there* will be *a large* number of interesting clinical cases at the Eye Hospital. Surgeons who desire to attend this gathering will be accommodated with board and residence in Keble College at the rate of 7*s.* 6*d* per day. They will meet at dinner on Thursday, July 25th, and the meeting will close after breakfast on Monday, July 29th. There will be morning service in Keble College Chapel at 8 on Sunday and *after breakfast* a launch will leave Folly Bridge at 10 to go down the river to Reading.

HER Royal Highness Princess Louise, Duchess of Argyll, has accepted the office of patron of the London *Temperance Hospital.*

ON Tuesday, July 2nd, at 4 P.M., at the Westminster Hospital, the Right Hon. Alfred Lyttelton, K.C., M.P., will *distribute the prizes gained in the hospital* medical school.

ASSOCIATION OF PHYSICIANS AND SURGEONS OF THE SOCIETY OF APOTHECARIES.—This association will hold a dinner at the Restaurant Frascati, 32, Oxford-street, *London,* W., *on Thursday, July 4th,* at 8 P.M. *All* Licentiates and their friends (ladies or gentlemen) are *invited. Tickets (single 7s., double 13s.)* may be obtained from Mr. Gerald Dalton, Cranbourn Mansions, Cranbourn-street, *London,* W.C., or from *Dr.* A. Rivers-Willson, 42, Wellington-square, Oxford.

POOR-LAW MEDICAL OFFICERS AND CLUBS.—*At a recent meeting of the Bideford (Devon)* board of guardians the business included the appointment of a medical officer for the Hartland district. Before the election letters were read from several clubs and friendly societies in the neighbourhood praying that the board would make the election conditional on the willingness of *the* officer appointed to take medical charge of their clubs, as there was a great difficulty in securing the services of a medical man for this office. They further stated that if this were not done it would have the effect of throwing a great number of their members on parish relief, especially poor women who were at present unable to obtain the services of a medical man when they were sick. One of the societies complained that although it had been without a medical contract since the beginning of the year yet "by great efforts of kind friends and extra subscriptions it had paid bills for only four juvenile members amounting to £3 9*s.* for very little attendance and advice." Another club stated that its medical officer's fees for last year amounted to £25 16*s.* It was further *stated that Mr. A. L. Martyn, one of the* candidates, was unwilling to accept the club's terms of office. Another candidate, Dr. Peter Lowe, had written to the clerk to inquire what fees he would get from the clubs. After receiving his reply he had sent in his application and it was considered that he would accordingly be willing to undertake the clubs if appointed to the district post. In reply to the suggestion that the appointment should be made conditional on such acceptance of the clubs the chairman stated that the Local Government Board would not recognise such a condition. Dr. Lowe was subsequently unanimously elected. It appears that there has been considerable local feeling in favour of the appointment being given to a practitioner who was willing to undertake *the clubs.*

THE COLONIAL NURSING ASSOCIATION.—The annual meeting of the Colonial Nursing Association was held at Grosvenor House on June 14th, when Princess Henry of Battenberg, patroness of the association, was present. Lord Ampthill *presided. The object* of the association is to provide trained nurses for the British colonies and dependencies and for British communities abroad both for private and hospital work. The report for the year ending April, 1907, shows a steady increase in the number of nurses employed. The number of nurses engaged during the year was 167, of whom 121 were in Government service and the rest in private employment. It is certainly a matter for reflection, as Lord Ampthill pointed out, that considering the importance *of* the *objects* of the association its members should number only about 112, while its income amounted to the small sum of £475, half of which was contributed by *Sir* Alfred Jones. The number of people who have relatives in distant parts of the empire cannot be small, and at a *time* when imperialism is preached from the housetops it is *singular* that greater interest should not be taken in the work of the association. Mr. Austin Chamberlain, in moving the adoption of the report, said the work of the association ought to appeal to every British citizen, for it was helping to *discharge* one of our imperial responsibilities. Men of our own race who gave the best years of their lives to the *public* service in tropical and semi-tropical regions had to face many dangers and difficulties against which no human foresight could guard, but we could at *least* ameliorate their sufferings in illness and save precious lives risked in the service of the empire. In nearly all our dependencies there were Government Hospitals but many a man was stricken down far away from a hospital and had to seek skilled nursing outside such institutions or remain dependent on servants of another race who were often ignorant and careless. How great the needless sacrifice of life had been in the past owing to the lack of skilled care and nursing he did not care to contemplate. Nursing was essentially women's work and the only way in which skilled suitable nurses could be obtained was by training and selecting them at home. The association equipped nurses when necessary for the particular country to which they were going and when they returned invalided home looked after them until they were able to recommence work. It was very noticeable that a great improvement had taken place in colonial hospitals since the association was started. This, he thought, was not unconnected with nursing sisters who had been trained in properly equipped hospitals at home. He appealed for support, not only to private persons who had friends abroad, but to the great mercantile houses whose existence was closely connected with the development of our colonies and dependencies. Sir George Goldie drew attention to the imperial value of the health of officials in places where a breach of continuity in administration might lead to serious troubles among the natives. Lady Piggott, Sir Edward Noel-Walker, and Mrs. Weston Devenish also supported the adoption of the report, which was carried unanimously. Votes of thanks to Princess Henry of Battenberg, to the Duke and Duchess of Westminster, and to the chairman concluded the proceedings.

Parliamentary Intelligence.

NOTES ON CURRENT TOPICS.

The Prohibition of Medical Practice by Companies Bill.

Lord HYLTON has given notice that when the Prohibition of Medical Practice by Companies Bill comes again before the House of Lords he will move as an amendment that the officers of offending companies shall be liable to the penalty provided in the measure quite irrespectively of the fact that the contravention was knowingly and wilfully permitted. This Bill, having now passed through its Committee stage in the House of Lords, is set down for third reading on Wednesday, July 3rd.

The Food and Drugs Amendment (Scotland) Bill.

Mr. MITCHELL-THOMSON has introduced a Bill into the House of Commons to amend the Sale of Food and Drugs Acts, 1875 to 1899, as they apply to Scotland.

HOUSE OF COMMONS.

WEDNESDAY, JUNE 19TH.

The Medical Aspect of Shot Drill.

Mr. H C. LEA asked the Secretary of State for War whether soldiers were still subjected to shot drill in any military prisons or detention barracks, either at home or abroad, and, if so, considering the consensus of medical opinion that existed as to the injury which this form of punishment did to the physique of the soldier, whether he would abolish it forthwith.—Mr. HALDANE replied Shot drill is no longer carried out in military prisons or detention barracks, either at home or abroad, although the consensus of medical opinion is not against this form of punishment, provided that it is under proper supervision. In fact, its abolition was not based on medical advice but on the substitution of drill, gymnastics, musketry, &c., for "hard labour."

The Barrow Drainage Problem

Mr. MEECHAN and Mr. KILBRIDE addressed a series of questions to the Chief Secretary to the Lord Lieutenant of Ireland drawing attention to various medical evidence given before the Barrow Drainage Commission, 1885, to the effect that large areas of country in the neighbourhood of the Barrow were so badly drained and so frequently flooded that the health of the public was prejudicially affected thereby. Both honourable Members asked what steps the right honourable gentleman proposed with a view to providing a remedy for the flooding —Mr BIRRELL replied: I have already answered a similar question put to me by an honourable Member this session I have fully explained to him that legislation is necessary before any large drainage schemes can be undertaken and that no such legislation can be introduced until full consideration has been given to the recommendations of the Arterial Drainage Commission whose report has been recently received. The question of arterial drainage in Ireland is one of considerable magnitude and I understand that the expenditure of some millions of public money would be necessary to give full effect to the recommendations of the Arterial Drainage Commission. It must be obvious that I cannot give any undertaking this session as to the introduction of legislation on the subject

The Fees of Vaccination Officers

Captain FABER asked the President of the Local Government Board whether, seeing that the granting of exemption certificates to conscientious objectors to vaccination was a matter over which vaccination officers had no control, and that the receipt of exemption certificates entailed as much clerical and statistical work upon vaccination officers as did vaccination certificates, he could see his way to insert a claus the new Vaccination Bill to provide for the payment to officers of a fee for the registration by them of exemption certif the same manner as was now provided for the registration of cates of successful vaccination.—Mr. BURNS replied I have occasion to consider this matter and I do not see my way to the insertion in the Bill of a clause to the effect suggested.

THURSDAY, JUNE 20TH.

Public Health in Belfast.

Mr. CHARLES DUNCAN asked the Chief Secretary to the Lord L tenant of Ireland whether he was aware that the Belfast S Shipping Company had a number of imported labourers living vessel in the harbour, whether he was aware that a number of labourers were reported to be seriously ill, and that several had alre been removed to Belfast Hospital, and what steps were proposed to taken to insure that this menace to the health of the city was abat The honourable Member in the course of a further question as whether the right honourable gentleman would take steps to see t the medical officer of health of the city of Belfast was informed t several cases of fever had occurred amongst the imported labourers present on board a vessel in Belfast Harbour, and whether he wo take such action as to insure that the medical officer of health car out his duties in an efficient and impartial manner regardless of interests of shipping and other companies —Mr. BIRRELL (reply to both questions) said: The Local Government Board has a special investigation made by one of its medical About 150 imported labourers are living in a steamship in Harbour. Two men have had to be removed to hospital surgical treatment in consequence of accidents, but no case of tious disease has occurred and none of the men have been seriously The medical officer acting for the port sanitary authority visits ship daily and both the public health authority of the and the port sanitary authority are fully alive to the of exercising a strict supervision over the vessel. The Local ment Board's medical inspector found the ship to be very The total number of men living on board, including the crew, is The ship is licensed by the Board of Trade for 356. The Local ment Board is satisfied that the facts of the case do not constitut menace to the public health of the city and no circumstance calling its intervention has arisen.—Replying to a supplementary Mr. BIRRELL said that he was satisfied that the medical officer and port sanitary authority had done their duty.

Cerebro spinal Fever in Belfast.

Mr. SLOAN asked the Chief Secretary to the Lord Lieutenant Ireland whether, in view of the fact that the recent spotted fe scare in Belfast caused a decrease in the average attendance at many the national schools, that the National Commissioners of Educati had notified the withdrawal of salary from teachers where attendanc had not reached the standard, and that rule 83 (b) provided for the exceptional cases, he would recommend the Board to continue t grant for an additional period of insufficient attendance.—Mr BIRRE replied (by written answer): The Commissioners of National Educ tion inform me that in cases in which the attendance has be exceptionally reduced owing to the spotted fever or any epidemic, they have exercised their power of continuing the grants assistants and will continue to exercise that power in proper cases.

Food Regulation Bill

Mr. ALDEN asked the President of the Local Government Bo whether, in view of the delay in proceeding with the Food Regulatio Bill and the importance of that measure, he would ask for Governme time in order to facilitate its passage into law.—Mr BURNS (by writte answer) replied The Bill is now awaiting second reading I cannot present say when this stage will be taken, but I shall, of course, b very glad if time can be found for this purpose

Cancer Research in India.

Mr WEIR asked the Secretary of State for India, having regard t the fact that the Command Paper entitled Statement Exhibiting th Moral and Material Progress and Condition of India, 1905-06, declare that very valuable results had been obtained by the Plague Investiga tion Committee, whether he would consider the expediency of appoint ing a committee to inquire into the prevalence of cancer in India an the measures taken to combat the disease.—Mr MORLEY furnishe the following written answer: The investigations which the honour able Member desires are already being prosecuted in India by th Imperial Cancer Research Fund in coöperation with the Governmen of India. Arrangements have been made for the systematic collectio of data as to the prevalence of the disease in India and for the trans mission of the same by medical officers to the Cancer Research Fun for examination and record The research work which the Fund i carrying on will guide the Indian medical authorities in the adoption of measures for combating the disease, which relatively to plague ha a very slight effect on the health of the general population of India.

Insanitary Barracks

During the afternoon a debate arose on the report of an Army Vote of £2,436,000 for the expenses of barrack construction, &c., and severa speakers complained of the insanitary condition of barracks in variou parts of the kingdom

Viscount TURNOUR said that Piershill barracks, Edinburgh, were not in a fit state to hold troops, and owing to the insanitary conditions the soldiers had suffered considerably from diphtheria and other diseases. Nothing had been done to remedy this state of affairs He also asked why the Government had not put the Preston barracks at Brighton into a proper sanitary condition

Mr MITCHELL THOMSON and other speakers asked whether it was the view of the Government that the Piershill barracks were insanitary If they were insanitary why were troops quartered there at all? Why were they more suitable for artillery than for cavalry?

Mr. BUCHANAN, the Financial Secretary to the War Office, in the course of his reply, said that Piershill was not an insanitary barrack A medical commission was sent down last year to examine it, and the members of it reported that it could not be condemned as an insanitary barrack. But it was a very inferior barrack The annual rate of sickness was not very high, but there had been a good deal of sickness in it from time to time. The situation was not a good one, and there was a sewage farm near it. The barrack, however, was not dangerous and e War Office intended to keep troops in it. When the Scots Greys re moved out of it there would be a further sanitary inquiry into the dition of the barrack. As it was impossible within a short time to ld a cavalry barrack of the requisite size in Scotland the War Office ded to have Piershill put into proper condition. The condition of hill had often been brought under the notice of the late Govern-, but it considered that there were other services which were e urgent and it spent the money at its disposal on those other ices. The present Government had endeavoured with the much e limited resources which it had at present to deal with the t urgent services, and it looked forward to constructing a lry barracks in Scotland as one of the most prominent needs of the re.

r. Balfour said that if the reasons for not keeping cavalry at hill were good, surely they were as good for not keeping artillery e. The Government should make up its mind whether it was a e where troops should be kept and whether it was insanitary or not.

r. Buchanan (interposing) explained that "insanitary" had a nical meaning. The War Office asked the committee which it t down to report whether the barrack was insanitary or not. If it been reported "insanitary" the barrack would have had to be demned.

r. Balfour (continuing) said that the barrack apparently was ealthy but not insanitary. He urged the Government not to let objection to defraying works out of loans instead of out of the imates stand in the way of providing healthy accommodation for the ps.

r. Claude Hay called attention to the condition of Perth barracks, ch he said was nothing less than a scandal. They were old and out ate from every point of view of modern sanitation and comfort.

r. Gulland remarked that it had been stated that there was a age farm near Piershill barracks. The corporation of Edinburgh however, now resolved that these irrigation meadows were not thy and steps were being taken to do away with them. That would eve the situation as regarded Piershill.

fter further discussion the motion was agreed to by 164 votes to 40.

Monday, June 24th.

The Public Health Acts.

r Francis Channing asked the President of the Local Government rd whether he would introduce, either in the present or the next on of Parliament, a Bill consolidating and bringing up to date the lic Health Acts and the provisions of amending Acts.—Mr. Burns , in reply: It would not be practicable to introduce a Bill to solidate the Acts referred to during the present session. I do not k that at the present time I could give any pledge as to legislation this purpose next year.

The Compulsory Notification of Pulmonary Tuberculosis.

r Francis Channing asked the President of the Local Government rd whether he had now obtained a report from the Scottish Local ernment Board as to the working of compulsory notification of monary tuberculosis in certain towns in Scotland; and, if not, ether he would obtain such detailed report and lay it before Parlia- t.—Mr. Burns answered: I am not aware that the Scottish Local ernment Board has made any report on the working of the com- ory notification of pulmonary tuberculosis in certain towns in land. The question whether any such report should be made and before Parliament is hardly a matter for me. It appears to be one my right honourable friend the Secretary for Scotland.

r Francis Channing asked the President of the Local Government rd whether the report of Dr. H. T. Bulstrode as to the sanatoriums pulmonary tuberculosis in England and Wales and as to voluntary compulsory notification of pulmonary tuberculosis, which was ed on April 15th to be in the press, would be issued before the vote the Local Government Board was taken.—Mr. Burns replied: Dr. strode is engaged in revising the proofs of his report, but there is a siderable amount of work to be done upon it, and I cannot under- e that it will be issued before the vote for the Local Government rd is taken.

The Sewage of Dumbarton.

r. Robert Duncan asked the Secretary for Scotland whether he aware that the sewer pipes of the burgh of Dumbarton were being ended towards the centre of the river Leven, whether this action the concurrence and sanction of the Local Government Board; , if not, whether steps would be taken by the Board to compel the gh to adopt a satisfactory system of sewage purification.—Mr. clair said in answer: I have no further information since my reply the honourable Member's former questions. The sanction of the al Government Board to the extension of the sewer outlets is not uired nor has it any power to compel the local authority to pt a system of sewage purification unless it can be shown that such ential in order to remove a public health nuisance. Arrange- ts have, however, been made for a joint inquiry by the inspector er the Rivers Pollution Act and the medical inspector of the Board.

Meals for Necessitous School Children.

r. Brooke asked the President of the Board of Education how y of the local authorities in England and Wales had thus far availed mselves of the Provisions of Meals for Indigent Children Act, passed session, and what were the names of those authorities.—Mr. Renna answered: Except in cases where it is desired to spend ey from the rates upon the purchase of food local authorities are required by the Act to inform the Board of Education of their pro- dings under it, and I have therefore no complete information as to authorities who have in one way or another taken advantage of its isions. The following seven authorities have been authorised by Board under section 3 of the Act to expend moneys out of the rates n the purchase of food: Acton Manor, Barry, Birmingham, Crewe, ersfield, Manchester, and Nottingham. Similar applications from [illegible] and Cannock have been received.

Women Medical Referees.

Mr. Ramsay Macdonald asked the Secretary of State for the Home partment whether, having regard to the increased number of female [illegible] affected by the new Workmen's Compensation Act, it was pro- ed that at least one medical referee in each district should be a woman [illegible]. Mr. [illegible] put a similar question.—Mr. Gladstone, replying to both questions said: The question of appointing women medical referees for the purposes of the new Workmen's Compensation Act is under my consideration.

Tuesday, June 25th.

Vaccine for the Army.

Answering Mr. Lupton,

Mr. Haldane said: The estimated yearly expenditure from army votes for the production of vaccine matter amounts to £410, towards which the Admiralty makes a contribution of £250 for the vaccine supplied to the navy.

The Government and Tropical Medicine.

Colonel Lockwood asked the Under Secretary of State for the Colonies what amount was contributed by the Imperial Government towards the maintenance of the Tropical School of Medicine at Liverpool; what was the total cost of maintenance of that hospital and what amount was contributed by the Government of the Congo; and what sum, if any, was contributed by the Government to similar hospitals in London.—Mr. Churchill furnished the following written answer: A sum of £500 a year is contributed by the Imperial Government to the Tropical Diseases Research Fund, administered by the Secretary of State for the Colonies, and an annual grant is made from this fund to the Tropical School of Medicine at Liverpool. The amount of the grant for the present financial year is £500. The school is not a Government institution, and I am unable to say what is the total cost of its maintenance and what amount is contributed by the Government of the Congo. An annual grant is also made from the fund to the School of Tropical Medicine in London. The amount of the grant to that school for the present financial year is £1000, with an additional grant of £1000 to be spread over three years, for the purpose of creating the appointment of a pathological entomologist at the school.

Wednesday, June 26th.

Patent Medicines and Alcohol.

Sir Gilbert Parker asked the Secretary of State for the Home Department, whether official tests were made of patent medicines offered to the public as to the amount of alcohol which they contained; whether there was any limit to its use in patent medicines; if so, what was it; and what penalties were attached to misuse.—Mr. Asquith (The Chancellor of the Exchequer) replied: Samples of medicines are from time to time tested at the Government laboratory in order to ascertain whether they are sufficiently medicated to be entitled to the privilege of sale without a spirit licence. There is no limit to the use of alcohol but in every case there must be sufficient medication to secure that the preparation cannot be vended as a beverage. The sale as a medicine of any article not entitled to be regarded as a medicine would subject the offender to the penalties applicable to the unauthorised sale of spirits.

THE Chief Inspector of Factories, Home Office, S.W., gives notice of vacancies as Certifying Surgeons under the Factory and Workshop Act at Knaresborough, in the county of York, and at Blackpool, in the county of Lancaster

Births, Marriages, and Deaths.

BIRTHS.

JAYNES.—On June 21st, at Jamaica-road, London, S.E., the wife of Victor A. Jaynes, Surgeon, of a son.

STOCKWELL.—On June 23rd, at Leeds, the wife of G. B. St. Clair Stockwell, M.B., of a son.

MARRIAGE.

HARRISON—BRADFIELD.—On May 15th, at Indwe, South Africa, Reginald Temple Harrison, M.R.C.S., L.R.C.P., to Jessie Louise, second daughter of the Hon. J. L. Bradfield, ex-M.L.C. Cape Colony

DEATH.

O'NEILL.—On June 22nd, at Queen's-road, Hertford, Georgie, wife of Robert O'Neill, aged 30 years.

N.B.—A fee of 5s. is charged for the insertion of Notices of Births, Marriages, and Deaths.

Notes, Short Comments, and Answers to Correspondents.

EXAMINATION ODDITIES.

THE following are some answers given to a well-known surgeon in an examination for elementary anatomy, hygiene, and first aid. He says, in forwarding them to us, "They seem to me to be amusing enough for publication; I have not altered either the spelling or the construction of the sentences":—

> The brain is composed of three sections: the cerebrum, *cellebellum* and the meddulla oblongata: the cerebrum is contained within the *bones of the skull and is of convolationary* shape.
>
> Typhoid fever is the result of tainted *effuria* and sound *respirating* organs are frequently effectual against it, and a salutary atmosphere will prevent such occurrences.
>
> Ague is the result of defective excretion through the pores of *the skin, the skin becomes chocked* and unable to perform its functions.
>
> Measles result of bad smell. *Avoid them.*
>
> *Frost-bite.* Take patient into a cold room and gradually induce warmth by enclosing in warm clothes, this is a gradual treatment and no rubbing must take place, otherwise the organ or flesh might fall off.

CYCLE SADDLES.

To the Editors of THE LANCET.

SIRS,—If "Algebra" is anxious for a suitable saddle I can confidently recommend Christy's anatomical adjustable saddle, 12s. 6d. I have been cycling *from* 13 *to* 15 years and *for* over ten years have been using this make as well as the plain Christy saddle. I have two bicycles and one has the adjustable and the other the plain Christy, and since using them I have never had an hour's trouble from perineal pressure. I was driven to use them by two bad attacks of prostatic inflammation, and the result of using a saddle with a division of, say, three-quarters to one inch from front to back of centre of saddle, and consequently no danger of pressure on perineum, has been a real blessing. I give the saddle a slight *downward* and *forward* tilt and find no inconvenience from it. It *must be* tilted; the amount is a matter purely of taste.

I am, Sirs, yours faithfully,

Cardiff, June 21st, 1907. H. L. HOOPS.

PS.—I do all my work on a bicycle.

To the Editors of THE LANCET.

SIRS,—Replying to "Algebra's" query I have much pleasure in stating that a saddle is made by Pattinson which absolutely obviates all perineal pressure. The essentials of this saddle are that it consists of two comfortable pads (divided by a median groove) *for* the support of the ischial tuberosities. The tilting with such a saddle is a matter of personal idiosyncrasy, but the best result is obtained by using the saddle absolutely *horizontally.*

I am, Sirs, yours faithfully,

H. WHEATLEY HART, M.D. Durh.

West Kensington, June 24th, 1907.

To the Editors of THE LANCET.

SIRS,—In answer to your correspondent "Algebra" I would advise him to try a "Christy" saddle. I have ridden one *of these saddles* ever since they were brought out and find it most comfortable. I am bound to say, however, that other persons who have tried my saddle say that *it is not comfortable.* But then, no one saddle will fit two people, any more than a boat or a gun will. As to the tilt at which the saddle should be placed, "Algebra" must find that *out for himself,* for no one can advise him on this point.

I am, Sirs, yours faithfully,

ETONENSIS.

To the Editors of THE LANCET.

SIRS,—As a cyclist of many years' experience I am pleased to inform "Algebra" that the best cycle saddles are those without a peak, such as the Christy saddle.

It takes a little time for a rider who has been accustomed to ride a saddle with a peak to get used to the other kind, *but after he has got* into the way *of it* he will never go back to the other and, I think, barbarous seat.

I am, Sirs, yours faithfully,

June 25th, 1907. *DERBY.*

OVINE TERATOLOGY.

IN the *Scientific American* of June 15th Dr. C. R. Stockard of Columbia University gives an illustrated description *of a remarkable* malformation of two lambs born in the *same flock* of sheep on a farm in North Carolina. The first of these lambs was born in the beginning of February. It was without any indication of limbs but was *perfect* in every other respect, having a well formed head and body and a long tail. Both the lamb and its mother were black. A second lamb identically like the first, except that it was white instead of black, was born on the same farm in the latter part of April. Th one had the same father as the former legless lamb but a different mother, both of its parents being white, whereas the first lamb had a black mother as already mentioned. Dr. Stockard says that animals presenting certain abnormalities may breed true to their peculiar form and that Darwin had described as instances of this kind the black-japanned peacock, the turnspit dog, and the "Ancon ram." The "Ancon ram" was a peculiar long-bodied sheep with short crooked legs, born in Massachusetts about 1791. These sheep existed in New England for 60 or 70 years, and were then in some way allowed to become extinct. Albinos are the most common examples of animal mutations of this description.

HYPODERMIC ADMINISTRATION OF ATOXYL.

To the Editors of THE LANCET.

SIRS,—I should like to ask any of your readers who have had experience of this method of administration of atoxyl whether they have had any unpleasant results. In two cases in my experience a hæmorrhagic bleb rose very shortly over the site of the injection followed by a slough of the superficial layers of the epidermis. The injections were made subcutaneously. The formula used was: Atoxyl, gramme ¼; aq. ad 1 c.c.

I am, Sirs, yours faithfully,
T. W. S. PATERSON, M.B. Cantab.
King William-street, E.C., June 24th, 1907.

WANTED—SUGGESTIONS FOR TREATMENT.

"ENQUIRER" asks readers of THE LANCET for information and suggestions that might guide him as to the treatment of the following case. The patient, a man, aged 37 years, has marked swelling of the eyelids, both upper and lower, with reddening of the skin over them, and redness and roughness of the skin between the eyes and on the forehead. A very unsightly appearance is thus produced, more especially as there is also a bulbous look about the nose. In addition, there is baldness and the patient wears spectacles for myopia. The swelling of the eyelids came on rather suddenly seven years ago, and a good deal of the swelling can be temporarily pressed away with the finger, giving the impression of inflation of the skin with air. The heart is sound and the urine is normal. The intellect is good and the family history is good; the mother, however, has had eczema. The treatment tried has been thyroid extract, suprarenalin, iodide of potassium, mercury, and arsenic. Collodion has also been used as a paint.

THE COST OF A UNIFORM.

A CORRESPONDENT asks our readers for information concerning the cost of uniform and training at Aldershot incurred by joining the Army Medical Reserve. He hopes that some Army Medical Reserve officer will supply him with particulars.

◆

Mason.—We consider that C's action as described to us by our correspondent savours of sharp practice.

COMMUNICATIONS not noticed in our present issue will receive attention in our next.

Medical Diary for the ensuing Week.

don School of Clinical Medicine (Dreadnought Hospital, reenwich.)—2.30 p.m.: Operations. Out-patient Demonstrations:— a.m.: Surgical and Medical. 11 a.m.: Eye.

EDITORIAL NOTICES.

is most important that communications relating to the orial business of THE LANCET should be addressed *tirely* "TO THE EDITORS," and not in any case to any leman who may be supposed to be connected with the orial staff. It is urgently necessary that attention be n to this notice.

especially requested that early intelligence of local events aring a medical interest, or which it is desirable to bring nder the notice of the profession, may be sent direct to this office.

tures, original articles, and reports should be written on ne side of the paper only, AND WHEN ACCOMPANIED BY BLOCKS IT IS REQUESTED THAT THE NAME OF THE UTHOR, AND IF POSSIBLE OF THE ARTICLE, SHOULD BE WRITTEN ON THE BLOCKS TO FACILITATE IDENTIFICATION.

ters, whether intended for insertion or for private information, must be authenticated by the names and addresses of their writers—not necessarily for publication.

cannot prescribe or recommend practitioners.

al papers containing reports or news paragraphs should be marked and addressed "To the Sub-Editor."

ters relating to the publication, sale and advertising departments of THE LANCET *should be addressed "To the Manager."*

cannot undertake to return MSS. not used.

MANAGER'S NOTICES.

THE INDEX TO THE LANCET.

HE Index and Title-page to Vol. I. of 1907, which is pleted with the issue of to-day, will be given in the next ber of THE LANCET.

VOLUMES AND CASES.

OLUMES for the first half of the year 1907 will be dy shortly. Bound in cloth, gilt lettered, price 18*s*., iage extra.

Cases for binding the half-year's numbers are now ready. th, gilt lettered, price 2*s*., by post 2*s*. 3*d*.

To be obtained on application to the Manager, accompanied remittance.

TO SUBSCRIBERS.

WILL Subscribers please note that only those subscriptions which are sent direct to the Proprietors of THE LANCET at their Offices, 423, Strand, London, W.C., are dealt with by them? Subscriptions paid to London or to local newsagents (with none of whom have the Proprietors any connexion whatever) do not reach THE LANCET Offices, and consequently inquiries concerning missing copies, &c., should be sent to the Agent to whom the subscription is paid, and *not* to THE LANCET Offices.

Subscribers, by sending their subscriptions direct to THE LANCET Offices, will insure regularity in the despatch of their Journals and an earlier delivery than the majority of Agents are able to effect.

THE COLONIAL AND FOREIGN EDITION (printed on thin paper) is published in time to catch the weekly Friday mails to all parts of the world.

SUBSCRIBERS RESIDING IN CANADA can have the thick instead of the thin paper edition if they desire it, without increase of subscription, on communicating with the Manager.

The rates of subscriptions, post free, either from THE LANCET Offices or from Agents, are :—

FOR THE UNITED KINGDOM.		TO THE COLONIES AND ABROAD.	
One Year	£1 12 6	One Year	£1 14 8
Six Months	0 16 3	Six Months	0 17 4
Three Months	0 8 2	Three Months	0 8 8

Subscriptions (which may commence at any time) are payable in advance. Cheques and Post Office Orders (crossed "London and Westminster Bank, Westminster Branch") should be made payable to the Manager, Mr. CHARLES GOOD, THE LANCET Offices, 423, Strand, London, W.C.

TO COLONIAL AND FOREIGN SUBSCRIBERS.

SUBSCRIBERS ABROAD ARE PARTICULARLY REQUESTED TO NOTE THE RATES OF SUBSCRIPTIONS GIVEN ABOVE. It has come to the knowledge of the Manager that in some cases higher rates are being charged, on the plea that the heavy weight of THE LANCET necessitates additional postage above the ordinary rate allowed for in the terms of subscriptions. Any demand for increased rates, on this or on any other ground, should be resisted. The Proprietors of THE LANCET have for many years paid, and continue to pay, the whole of the heavy cost of postage on overweight foreign issues; and Agents are authorised to collect, and generally do so collect, from the Proprietors the cost of such extra postage.

The Manager will be pleased to forward copies direct from the Offices to places abroad at the above rates, whatever be the weight of any of the copies so supplied. Address—THE MANAGER, THE LANCET OFFICES, 423, STRAND, LONDON, ENGLAND.

METEOROLOGICAL READINGS.

(*Taken daily at 8.30 a.m. by Steward's Instruments.*)
